hummmm.can any body help with the plans od size of the home made hex bean ..i would like it to do 10-40 meters ...
iv look in the post on here and just came up with a headack..
need the plans where to put the wire ,,what way to put it,,where to stop and all so the poles are for the size beam .....
ok thanks for any help from any one

all the best andy 73,s

Andy,

To the best of my knowledge noboby has attempted a 10-40M antenna. I would imagine the interactions between elements would make it unmanigable, even if you could get over the physical design headaches of such a beast.

I would recommend you start with a 5-band antenna, for which there are well documented designs on the Group. Good luck, but I won't hold my breath waiting for your designs!!

Best Regards

David, VK2DPD/M0DPD

>>(a Cabella Crappie fishing pole)cracked ...

I'm new to ham. I don't know if this has been mentioned. Just trying
to be helpfull. ...

Fishing rods should have a strong and weak side. The direction the
fishing line will pull on the rod should be the strong side. The
weaker side will give you tension with less chance of breaking the
rod. If you have a blank. You can find the strong side by rolling
the rod against the edge of a table while the butt is on the floor.
You do this while pushing a little on the rod for tension. The rod
will want to "settle" on the weak side.

I would like to mention. If you want fiberglass rod blank that is
very strong. Try a "Cal Star" fishing rod blank. You would be amazed
at how much bend these will take without breaking. I think this
stuff could take ice. They are guaranteed I think for life. I
wouldn't be surprised, if you called Cal Star and asked, that they
would guarantee them for usage on a hex-beam or quad. The longest I
see on a website (just looked) is only ten feet...I thought I had
seen longer. Also, for this use in antennas. If someone who knew
what he was talking about (not me) were to call Cal Star....He might
be interested in making blanks for this use? Or at least advising
for the best blanks....I'm still sure I've seen longer than 10 feet
from Cal Star.

The method they use for attaching eyelets to fishing rods is
actually extremely good. By this, I mean by wrapping thick thread
around the rod. They do double, and tripple wraps commonly. Usually,
one wrap set is under the eyelet. Then the others are over the
eyelet to hold it's feet on the rod. This actually increases the
strength of the rod instead of weakening it at that point. I think
it would be a great way to attach anchors for antenna wire.

I'm just trying to help here. Maybe good suggestions? Maybe
overkill? I hope this helps out?

I am aware that Traffie attempted a 30 & 40 m HB and found it to be not viable. Same was true for adding about any other band with the 40 m HB. In addition, adding 6 m to the HX-5Bi was found not to work adequately ... degraded performance too much. A good guideline to see if bands will work together is to look on www.hexbeam.com and see what combinations Traffie offers.

Although I am planning to put up a 40 m Hex-Beam in a few months, I would really like to have a 30 & 40 m HB. Not possible however.

1650. Graphite and Fiberglass

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-09-22 22:14:36 UTC
From: ralple
Topic: 1650 Message: 1650

Again, I don't know if this has been mentioned. I've just started looking at hex-beams, so I don't know all of what is out there on info.

Graphite won't take much abuse. Yes, it is nice because it's light. But good fishermen quit using graphite Salt Water rods because they couldn't take the abuse. In Salt Water, fishing rods get banged around alot. Graphite, when hit against something, chips easily. Then, where that chip occured, it will break more easily.

They do make a combination graphite and fiberglass blank. I think it is more for selling something to fishermen than performance.

The light yellow colored fiberglass isn't as good as the dark caramel/brown colored. You'll see the light yellow in Sabre, and some others. Also Seeker is kinda closer to the light yellow than the darker caramel color. Then they can add color to make these black...can't tell much by the color at that point.

From what I've seen at the Max-Gain site. It appears they have antennas pretty well covered? Looks like they're trying to keep the fiberglass light weight while performing. I think these rod blanks will be heavier. So, personally, I might only look at the Cal Star rod blanks for abusive environments where the light weight might have a problem.

I hope my comments are constructive to others?

RonP

1651. Max-Gain Fiberglass spreaders

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-09-22 22:38:31 UTC
From: dsimmons1999
Topic: 1651 Message: 1651

Adding to the spreader discussion, I just received an order from Max-Gain (http://www.mgs4u.com/fiberg.htm) for the spreaders on my homebrew hex-beam.

I ordered the following 8' pieces:

```
QTY Size Type
--- ---- ----
3 3/4" tube
3 1/2" tube
3 1/4" solid rod
```

Since UPS cost for 8' packages is really expensive, Max-Gain will cut the 3 pieces in half and then you have 6 of everything, avoiding the shipping surcharge. Be sure to ask them to sleve the tubes before cutting; that way you pay for 3 cuts instead of 9. The whole set was a bit over $70 shipped to the west coast.

The material seems pretty strong. These are definitely heavier than fishing pole blanks and should be more durable.

The only thing I'm concerned about is that the 1/4" rod is much more flexible than the larger tubes. If I pull up on the tip of a 11' assembly, the end thinnest piece does almost all the flexing, which is totally understandable. I'm planning on using a few spacers so the tubes are pointing up slightly and this should put the spreaders in about the right place for the wire junctions on the higher frequency bands. In other words, I'm still sorting out the geometry and base mounting.

Allen Bond at Max-Gain mentioned that he gets about a call per week asking about hex-beam spreaders and thinks this would be the best setup.

- Dave
KQ6RL

Usual disclaimers: no relationship with Max-Gain, just a customer.

Simple put, there is too much coupling due to the elements being
close together and their relative frequency. Gain and F/B were
adversely affected.

I went with Max-Gain also and used 6 3/4 tubes and 6 1/2 rods. Makes
a sturdy antenna.

hello to all.
iv been looking at all that has been posted well all most all,,
as u can see by the subject heading i have a small garden...
and im in a biult up town,,,,
i was trying to make a 10-40 meter hex beam but can see that it cant
be done ,,but,,
there is a 5 band hex beam mmmmm that sounds like it would be the
better thing to do as there so many ham bands to cover.
(has any one tryed with a atu to see if this antenna can go a few
more bands than the five it give u ??)
im not sure but i think the 5 band hex is about 30 ft across mmmmmm
as wide as my garden,,,
im getting stuck i duno what to do dont wont to upset the people
next door as there no gaps between the houses where i live....
mabe if this hex ant going to be any good to me as of the size can
any tell me. what can i do to get that type of performance..or..
shalll i make a smaller hex and atu it hummmmmm help lol

ok all the best to all 73,s andy

Yes, I have operated mine on 6, 30, 40 and 75/80 m. Some F/B in some cases and who knows the gain (or loss). In any case, I have make a number of contacts this way.

> im not sure but i think the 5 band hex is about 30 ft across mmmmmm

5-band Hex-Beam is just under 20' diameter, so would fit nicely.

Hi Jan,

One simple way is to put the pipe in a machinist "V" block and then
run a pencil down the length using the block lip as a guide. If you
don't have this fixture, you can make one easily by attaching two
boards together orthogonally. Of course, one side should be adjusted
appropriately to allow access to the pipe. I have used this method
many times over the years for a quick and dirty method. Of course,
when I'm in my shop, I just put the pipe in a lathe and make the mark.

Look in the files area Jim and you will find the equations you need
for element lengths and such. The mechanical portion will likely be
an interesting experience of experimentation for you.

You need to make a line the length of the tube, perfectly straight? Paint a surface, then touch the pipe to the wet paint surface. I don't think you could help but get a perfectly straight line that way.

its relatively simple. Model rocketry has a similar problem for fin alignment. You can use a piece of V shaped molding or angle iron to form the line you can draw along. if you do not have a piece of V shaped molding, use a handy doorframe. There are lots of 90 degree angles in a doorframe that will hold a piece of tubing still while you draw the alignment line.

when you start drilling, use a clamp and a drill press to make sure the bolts go straight through. It's a really not very hard but take your time, measure twice, drill once.

Put it in the "V" of a piece of angle iron. You can use one of the legs
of the angle iron to make a perfectly straight line.

It is an antenna software for calculations of the behavior of the antennas under RF signal. You can use this software to calculate the correct lenghts of the elements, to calculate the SWR , bandwith, front the back ratio , gain etc. for definite frequency.

You can find MMANA file for the best antenna wire sizes in "files" section of the group . I downloaded the software from internet and it is great.

Folks,

Members of the DXpedition to St. John, U.S. Virgin Islands, 3-13 October 2003, will be using a HX-5B Hex-Beam. They will be participating in the CA and PA QSO Parties as well. For more information about this DXpedition, see http://www.w3srl.com/.

Thanks for the pics Jan,So far it all looks very good.

The wire should do the job very well,however you should consider
measuring the diameter of the wire in MM. The designation 2.5 quadrat
is not known in the English speaking world..
MAW Jan,in New Zealand they are talking about 7/029 wire (good for 15
Amps)
In North America we talk about #14 wire (also good for 15 Amps)

Scott,

There should be a pdf file in the "Files" section, which has the dimensions for the 20M version. Can't remember the name, but it was one of the original articles written by Mike Traffie on the Hexbeam..

Hi Jan,
My 1st post on the reflector (although i`ve been lurking for a while).
Good to see you solved the marking problem and are progressing with
the fun part of construction.
Just for reference - a good way to hold a round tube for marking
and/or drilling is to put a `U` bolt with saddle on each end,just
tighten the nuts finger tight, align them on a flat surface and
tighten carefully without moving the bolts. The tube will sit firmly
on the `studs` of the `U` bolts while you mark or drill.

Best 73`s & good luck with your hex-beam project.

Colin

1677. Hexbeam vs. MA5B

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-10-10 23:10:42 UTC
From: ke4vpe
Topic: 1677 Message: 1677

Currently I am using the MA5B, and I am thinking about replacing it with a 5 band Hexbeam. Since the Hexbeam cost 2.5 times the cost of the MA5B, do you think it is worth the additional expense? Will the Heambeam significantly outperform the MA5B? I know that the Hexbeam will perform better on 12/17 meters, but what about 10/15/20?

Thanks,

RC

Hi RC,

Well, first of all, the HX-5Bi costs 50% more that the MA5B ($889 vs $599). I have never used the MA5B, but looking at the photo of the MA5B makes me confident that the HX-5Bi will beat it hands down. The MA5B appears to have 3 elements spaced on a 7' boom, with traps and capactive hats. In contrast, the HX-5Bi is a collection of 5 two-element beams, each having full size elements with no traps, etc.

Folks that I know that have switched from the conventional Yagi to the HX-5Bi comment on how quiet it is and how well it performs.

I think the question to ask IMO of Hex-Beam owners is if they had to make the decision again, would they buy the Hex-Beam again. In my case, I would unless I could have an antenna farm that isn't realistic! :-)

Maybe someone else has used the MA5B and can give you a first-hand opinion.

$889 may seem high, but it is well built, will last, and perform very well.

1680. hexbeam versus ma5b

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-10-11 18:46:33 UTC
From: kd6wd
Topic: 1680 Message: 1680

I have friends who have both of these antennas. One is kd6cys in the San Diego area. He loves the hexbeam. Another friend ny4pd in florida has the ma5b. I have a 2 element lightning bolt quad. The ma5b hears well but does not have quite as much transmission punch as the hexbeam. Claude (kd6cys) and I regularly work the same stations across the country with similar signal reports for my quad and his hexbeam. Brian ny4pd needs a bit more power with his ma5b than other stations in florida using hexbeams to my qth. Its about 1 s unit difference to my qth in Redding California on 17 meters. In my opinion, considering the short turning radius of these antennas they are both great. If you have the bucks get the hexbeam it works very well at lower heights. If you have a tower at 40 feet, the ma5b will work well and you save a few bucks. I am planning a move to florida and would like to be able to keep my quad. However, I would not have a problem purchasing either the ma5b or the hexbeam. I would just prefer the hexbeam because of the extra gain on 17 meters. I believe both of these antennas can use a radio shack rotor. If you can put up a bigger antenna try the Lightning Bolt quad. It will require a HamIV or Yaesu 800 to turn it without excessive wear. And at around $300 dollars delivered, its very good bang for the buck.

I picked you the $599 price on the Internet at
http://www.durhamradio.com/cushcraft-ma5b.htm.

In checking some more, Universal Radio states List Price: $473.39
Your Price: $369.95. You clearly found an evcen better price.

My interest in seeing what this little guy is about was increased
enough for me to look at the Cushcraft site. The parameters are
shown below. Weight is 26 lbs and HB is about 20 lbs.

On 12 and 17 m, the gain in dBi is just 1 and it has but one element.
So it isn't a beam at all on these bands, just a rotatable dipole.
On other bands, it has 2 elements. F/B isn't impressive. The affect
of the loading is evident in the 2:1 bandwidth. 90 kHz on 20 m is
not for me since I operate CW, PSK, RTTY, and SSB. Same on 15 m if
you operate CW and SSB. It might be a nice little 3-band, 2-element
beam (and dual dipoles), but the Hex-Beam eats its lunch IMO when you
consider F/B, gain, beam performance on all five bands, and excellent
operating bandwidth. So it is worth the extra $500 to have the HEx-
Beam performance on all bands? To me it would be again, but then not
to all I would guess.

Frequency, Mhz 10 12 15 17 20
Active elements 2 1 2 1 2
Gain, dbi 5.3 1.0 4.8 1 3.6
Front to back ratio 10 0 12 0 22
Side lobe Atten. 25 25 25 25 25
VSWR 2.1
bandwidth 665 Khz 110 Khz 255 Khz 100 Khz 90 Khz

Hello,

Is it worth the more money? I guess the question is what is your antenna support system like? If you are using a beefy rotor, then you could go with a nice 5 band Quad (like Lightning Bolt Antennas) which is about the same price as the MA5B. Do you have the room for a larger turning radius? Then the quad and/or a Tennadyne log periodic may do the trick for you (the Tennadynes start at 489.00 and have a 20 ft turning radius).

The Hexbeam allows you to fit alot of great features into a small package. You are not lowering radiation efficiencies by ANY type of loading. So if you have small space (like me), then the Hexbeam is perfect to replace your MA5B.

If you have a nice antenna support system, then by all means go with a quad and save some cash.

I still love my Hexbeam! It has allowed me to work SSB to countries I have never been able to reach before (like China!)

1684. Re: Hexbeam vs. MA5B

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-10-11 23:53:33 UTC
From: ke4vpe
Topic: 1677 Message: 1684

My MA5B is mounted at 30 feet. The mast is 30 feet of rigid conduit, and the rotor is a Channel Master rotor. I am restricted by a turning radius of 10 feet unless I remove a tree. My XYL already ruled against cutting down the tree. In addition, I have antenna restrictions (CCR), so the antenna can't be too large, and it can't be seen from the front of my home.

My MA5B works well when compared to my G5RV, but the F/S and F/B is not very good. On numerous occassions, I have heard DX on the MA5B and only heard static on the G5RV. The G5RV is installed at 35 feet in an inverted v configuration.

I really would like to improve my performance on 20 meters, since the MA5B is not broadbanded on this band.

Well how about that! Our good friends to the north use our $ sign
too. ;-)

Seriously though, the HB will do fine at 25'. Many are using it
around this height. Maybe a few will comment that are. It is
designed/tuned for the 20 m element to be at 42'. My HB is at about
35' (20 m elements) and does fine. Main difference is a raising of
the take-off angle as you go lower. This is the same for all Yagi
and such antennas of course. When you say 25', do you mean th3 top
of the mast, the base of the antenna or what. If it is where you
mount the rotor, the 20 m elements will be about 4' higher.

From the sounds of it, your best bet is to go with a Hexbeam if you want to replace the MA5B. I think the Hexbeam is a superior product in regards to radiation resistance compared to the loading that occurs in the MA5B. The Hexbeam is 9.4' turning radius, gives you gain on ALL bands (the thing sings on 17), and it is very unobtrusive. Your rotor will have no problem with it. I assume your mast is secured against the house or guyed.

I think the Hexbeam looks better as well (you know, the XYL factor! HIHI).

The other thing is that Traffie Technologies offers a 30 day money back guarantee if you are not happy with it. You are only out shipping. I will warn you though... only one has ever gone back! :)

So it sounds like in your installation, the Hexbeam would be your best bet. My Hexbeam (www.n8xe.com for details) is at 32' and it performs very well. I also have sound bytes of A/B comparisons between the Hexbeam and my dipole.

If you want, let me know and we can do a sched and we can do A/B comparisons. I know the rest of the guys would also have the same offer. Maybe tomorrow evening? Anybody else want in on this?

If price is a major consideration, make a HexBeam. It's pretty easy to do, the instructions are well documented on the group, and it would be a fraction of the price of the HX5i and the MA5B..

My hexbeam is at 25-27ft (that is the height of the very top) - it works well, undoubtedly it would work better at another 10ft up but I am very pleased with the performance. Whereas you can get near optimum performance of a hexbeam at this height, you would have to put the MA5B higher for it to achieve its spec.

I suppose it depends on its intended use: if you are not very active, like a rag-chew across your Continent, you could spend less and manage quite well with a MA5B. If you want to compete in pile-ups, do a bit of contesting then spend more and reap the rewards of a hexbeam.

Eric G0CGL.

1689. Two Hexbeam Questions

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-10-12 14:08:42 UTC
From: Dennis Spiess
Topic: 1689 Message: 1689

I just put up the 5 band HexBeam # 298 and have two questions for this group. I will call for tech assistances too!

1.) The antenna is tuning out of the band plan.... 2.0:1 band edges are: 14.05 - 14.50 (>2.0:1 below 14.05), 18.70 - 18.94, 21.00 is OK, 24,95 - 26.128, 28 is OK.
Any ideas how to tune to the bands?

2.) I do not have a balun / choke on the feedline. Will this possible help? Where should the choke be located? Right at the feed point or below the spreader?

The antenna is at 25 feet above ground. ~5 feet over the roof on a tripod. Feed Line drops almost vertcally to the ground then into a basement shack.

Thanks for your help
Den

1690. Measurements 20m homebrew hex.

Hi All.

I just made an 20m monoband hexbeam,
did some measurements using an AEA VIA-HF
antenna analyzer.

Antenna height +/- 3 meters above a flat roof(3m height),
Director element length 10,92m
Reflector element length 11,56m
Driven element spacing 0,18m
Reflector element spacing 0,11m
overall spacing 0,26m

I think vswr will go down if placed on a mast
at 12 meters above ground level,
also the resonance freq will go up slightly,
this beam is optimized for SSB..

Photos are placed in:
Photo Albums > SWR Plots > PH0DX 20m Monoband

Dennis,

I am wondering if it is reacting to something nearby like another antenna? I don't know if the balun will help you there. Anybody else have an idea?

Hello,

Regarding the reported VSWR issues:

1. Do you have metal guttering, metal flashing around the roof eaves and or house wiring in the attic or crawl space?
2. Does the VSWR change as you rotate the Hex?

If the answer to the above is "yes" the near field metal is the probable cause. To prove this out raise the Hex by at least 10'. Verify no other antennas that might possibly be resonant on the bands of concern are in the near field. Let us know what you are using to record the reported readings.

As to the balun,the recommended choice is to install 6 Amidon FB-77-1024 cores on the coax just below the Hex's base plate. This may or may not have a major affect on the VSWR readings. For more detail on this search the archives or contact Barry, W4WB. Keep us posted on your findings for further support.

Date: 2003-10-13 12:19:20 UTC
From: Dennis Spiess
Topic: 1689 Message: 1693

Doug,

Thanks for your input. I have had some more time to investigate the SWR. Yes, the SWR does change as I rotate the beam especially on 14, 18 and 24 mHz. There are directions where the readings are as reported and directions where the SWR is closer to what I would have expected for the antenna! These variations are consistant from band to band. The 'good' direction is consistant for all bands.
The only other HF antenna is a Butternut vertical for 30,40 & 80M. It is ground mounted 30+ feet from the Hexbeam.

I am using an Autek WM1 meter in the shack at the transmitter. I think it is pretty accurate. The SWR meter in the rig agrees with it.

The antenna is ~ 5 feet over the roof which is above a second floor apartment. I am sure there are wires in the ceiling under the roof. The entire house is aluminum sided but the antenna is pretty well centered on the roof and is 10+ feet from any aluminium.

I have new coax and the Palomar balun kit on order and was planning on installing both when they arrive.

It will not be easy to raise the antenna. It could be done but I will need to either replace the tripod, it is 3 foot high or raise the rotor up on a pole and guy it below the antenna. Then figure out how to get the antenna up the 10 feet onto the rotor.

Any ideas / suggestions would be appreciated.

I thought this would be easy.... stupid me.

1694. Re: Hexbeam vs. MA5B

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-10-13 12:39:46 UTC
From: Dennis Spiess
Topic: 1677 Message: 1694

My inputs, why I just bought a Hexbeam:

1. The Hexbeam is just wires. It will be good old reliable wires 10 years from now. No smoke, no mirrors, no traps, caps etc. to go bad or go out of tune. No aluminium to 'corrode' and stop working. There is nothing simplier or more reliable than a wire antenna.

2. My new Hex replaced a Butternut Butterfly which was pure magic (smoke and mirrors). The Butterfly never tuned well. Didn't receive too well, transmitted about the same as a dipole. As time went by it slowly lost what tune it did have. I did logged my second hundred countiries on my Butternuts (also have a vertical). Looking back most of the contacts on the small beam were @ 600+ watts!

3. Listening with the Hex is like putting megaphones in my ears WoW. It really captures the signals. Probalbly due to the full sized elements. MUCH more capture area. I NEVER heard my low voltage halogen lights before... guess I will have to quiet the them down now! (Anyone have any ideas?)

4. My wife, also a ham but not into cluttering the house with antennas, thinks the Hex is 'cute'.

All I need to do is get it stop 'seeing' my house below it which appears to be my problem.... refer to my thread on tuning.

Just my 2 cents

Hi Den,

You likely are suffering because of the siding, the proximate wiring unser the antenna, and perhaps metal ducting in the apartment's roof area. More than likely, the only cure is to get some more height. Even 3-5' would likely help. The HB is fussy about metal stuff underneath it too close.

Unless they have recently changed, the Palomar kit uses Type 43 material. After having played with many of the materials and studied their characteristics, Type 43 is not so desirable. The Type 73, 77, or 31 (31 is okay unless it gets hot ... its Curie temperature is about 100 C less than for the 77 or 73). 43 is good for VHF and UHF.

Hi Den,

I can't quite envision your tripod, but can you leave the rotator on or in the tripod? Can you then bolt the Hex to a length of 1" pipe, stab it into the rotator and use Dacron guys on a bearing ring just below the Hex? Traffie's HDX-30 mast might be a solution also even if you can't put it up at the full height. Don't hesitate to call Mike Traffie at his toll free number for ideas.

1697. Re: [hex-beam] Re: Two Hexbeam Questions

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-10-15 13:14:26 UTC
From: Dennis Spiess
Topic: 1689 Message: 1697

Doug,

It is just a small tripod I picked up years ago, about 3 feet high with the rotor sitting just above it.

I think I have the solution.
I am going to increase the height of the rotor above the roof to ~ 4 feet by replacing the pipe in the tripod with a longer one. I'll attach the rotor to the antanna / mast and rotate it up as one piece. The weight of the rotor/mast will counter the torque of the antenna. (The roof is very flat so working on it is easy.) I'll guy the bottom of the rotor with 5/16 dacron line...(I have been advised NOT to use wire guys, I see why now!) I just need to find one rafter under the shingles for a guy... perhaps a stud finder will do the trick. This will take a lot of strain off of the tripod. The antenna will be on top of a 5 foot of water pipe above the rotor. It should be very sturdy and will be at ~ 10 feet off the roof. The HamM should have no problem supprting the antenna un-guyed 5 feet above it.

I think this makes sense.... yes, I do like to plan and think out everything before I do it. I just did not foresee the interaction between the antenna and my house!
See any flaws?

If that is not high enough I will have to live with it. The SWR at worst case is livable now and can easily be tuned out with the rigs tuner. Any improvement will help.

In the process, I am changing the rotor to a HamM (the rotor up there now is a TR-44? Smaller than a HamM and no brake). The HamM has been in storage for a few years (Yes, it works, I have thoroughly tested it.). Putting in new feed line, and new rotor cable and the balun/choke at the bottom of the antenna.

Yes I will call Mike to discuss.

Thanks for all of your input. This is a great experience. My first new antenna in many years. So far the Hex has produced outstanding results. Fabulous sensitivity and the front to side / back ratio is outrageous. Station completely disappear if I am not aimed at them!

From: K8NKE
Topic: 1698 Message: 1698

i see some run the leads that connect the elements together on the outside of the center support and some put them on the inside. was wondering if it makes any difference. it would be a lot less trouble to run them on the out side.

Hi Dale,
My home brew 5 band hexbeam have a twin line outside of the center support. Feeder is connected at
the bottom side (10m element). I erected that antenna a year ago - no problems at all.

From: w6hb
Topic: 1689 Message: 1700

Hi Den,

Sounds doable. As long as the tripod and mast to the bottom of the rotator is solid, it sounds like it should work. Obviously the VSWR issues are having negligible effects on the performance. That is common news. The only other issue some observe when near field metals impact the VSWR readings is that susceptibility for RFI may be more prevalent due to the coupling into the surrounding conductors. Let me know how eveerything goes.

Den,

If the Palomar balun kit uses the split cores with the snap-on Nylon covers, cut off the "tits" that keep the assemblies from sliding on the jacket of the coax. Secure the toroids with a full over wrap of a good vinyl tape and seal it with PVC or CPVS cement. You can also used the black UV-resistent tyraps to center the stack where you want it on the coax just below the Hex plate. If you leave the "tits" on they will eventually wear through the jacket and allow water into the coax.

1702. HXL-17 monobander for 17M

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-10-16 00:48:26 UTC
From: na1a2001
Topic: 1702 Message: 1702

Performance is simply amazing. I can work the DX much easier than with my previous 2 element full size 5 bander cubical quad. I can receive signals that my Carolina Windom cannot or bearely audible. SWR is pure flat. F/B is about 2-3 S units. You simply have to try one out to believe it. Go to my website at http://www.qsl.net/na1a/Hexbeam/ to see pictures.
Any questions, feel free to e-mail me.

1703. Re: [hex-beam] Digest Number 420

Topic: 1703 Message: 1703

hi den never use a mast longer than 4 feet above any rotor, it put to much strain on the rotor bearings. sorry to have to give you this info den but i know of many who had problems from using a long mast. vy dirk

Doug,
The palomar kit is torroids that slip over the coax and are held on
by shrink wrap. I will put a layer of good tape over the wrap.
I have seen some RFI from the Hex where there was none before. I
fogured it was from the either the feed line or the coupling.
Hopefully it will get better once I raise things a bit on Saturday.

1705. New pictures in photomap PA2JJB

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-10-17 21:08:06 UTC
From: PA2JJB
Topic: 1705 Message: 1705

Hello everyone,
Put some new pics in my map. Could'nt find the right U-bolts; so I make them by myself. If you like to make those U-bolts by yourself, remember its cost you lots of time and nervs hi hi.
But after a evening and a morning I had make 12 U-bolts, not exactly the same in shape, but they do their job very well. I make them of 1/4 inch wire-piece a 3 foot long.
Yesterday I bought the last 3 bamboo's so this afternoon I was able to assemble my HEX-beam for the first time, to see if all my work was done well. Need some suggestions how i put my rotorpipe to the HEX-beam. The underside off my centerpipe is equal to the underside of the centerhub. Maybe I must put a smaller PVC-pipe in the centerhub and fix it with some screws.
My next step is to paint my centerhub in a gray-color so it will not be seen from the ground,
Then the trickyest part of all is to bend the bamboos in the right shape; but I have get some good suggestions from my collega Lourens PH0DX; and then it must be very easy to bent all 6 bamboos at the same time. He will write about that soon.
OK folks, hope I have informed you enough, and let you see and know what the next steps are in assembling this beautiful beam.

73's from

Here is a nice writeup I found on the Eham Elmer's forum posted by a very active amateur who has listened to many Hexbeams without having yet owned or operated one.

RE: Best antenna for the casual DX operator
Reply
by WB2WIK on October 17, 2003

I don't own one, but based on over-the-air signals I hear and work daily on the upper HF bands (20~10m), I can't help but recommend the 5-band Hex Beam (Traffie Technology). They are small, very lightweight, easy to rotate (no boom, so they can be turned by a rotor having no brake) and just seem to generate enormous signals, compared to stations in the same areas using other "small" antennas (MA5B, verticals, dipoles, inverted vees, etc). The difference is rather staggering, and if you're very active on the air, you'd already know it.

I make about 20~100 contacts daily, depending on the day, the propagation, and how busy I am! Usually about 20 QSOs after work and before dinner each weekday, and about 100 QSOs per day on weekends, just casually operating, DXing, ragchewing. I always ask about the other station's antenna (I'm much more interested in that than his equipment), and take prolific notes.

The strongest signals from any area always come from the "big aluminum" guys with huge beams on big towers, and there's almost no exception to this. The smallest signals from those same areas come from small antenna systems, indoor systems, low dipoles, poorly installed verticals and so forth. In between are stations using smaller beams, lower towers, and better engineered wire and vertical antenna systems.

When I consider space/weight/ease of installation/ease of rotation/wind loading and other factors, I have to conclude the Hex Beams may well be the best antennas on the market for those with limited space not wishing to install "heavy hardware." And, I don't even own one! I'm just going by how they sound on the air.

I do use beams on HF, and I'm sure I always will, but currently the most intriguing beams on the market (for me), and ones I do not yet own but *definitely will* someday soon are the Hex Beams and the Fluid Motion SteppIR beams. Both seem to work splendidly for their light weight, etc. Neither are "cheap," but, then, the antennas do a lot more work than the radio equipment does....

I have cooresponded with WB2WIK/6 in the past and he seems quite knowledgable about antennas. In fact, I wrote a vertical article for eham.net last year based on an article he wrote. (http://www.eham.net/articles/5225)

It's great to see this type of praise for the Hexbeam as the guy does not even own one.

73,
Jason

I have not been on the air much because I have been working on my amateur telescope... :(

1709. Re: Two Hexbeam Questions --> Update

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-10-20 12:17:44 UTC
From: Dennis Spiess
Topic: 1689 Message: 1709

All,
We, my XYL (N2RDX), and I had a very successful Saturday. The Hex beam was successfully raised to 10 ft. over the roof, new coax, balun, rotor, rotor wire and guys.
The results are almost perfect. The SWR is 2.0:1 or less for all bands, except 12M, at the bottom of the band and drops rapidly to < 1.5:1 for almost the entire band. The SWR changes less than 0.1 for the entire rotation around the compass! Inter-actions seem to be cured.
On 12M the SWR is still high for about half of the band then it drops off rapidly to 1.2:1. Once I have the time to plot out the exact curve I will call Mike Traffie and see if he has any ideas. My rigs tuner can easily bring the SWR down and deliver full power at 12M.
I want to thank you all for your input, especially W6HB who has stuck with me all week as I tried to finalize my plan of attack.
We re-insatlled our Butternut 8 band vertical, now slimmed down to 3 bands (80, 40 and 30), on Sunday ... a good honest vertical... makes us 8 band radio active on HF (finally).
We can't wait until the November SS.

Hi guys,

Well, Sweepstakes is right around the corner. I have not decided whether I will be operating QRP (for the CW contest) or not. My K2 would love to stretch her legs at working the contest. But her big brother, the IC746, is staring at me thinking, "You are going to use ME in the contest right?!?"

Either way... the Hexbeam will be active either way. I was so bumbed that I was not able to use it last year (I got it in September but did not put it up on the tower until Christmas Eve!)

I hope to work some of you in the contests this year...

73 es GL!

1711. Jamboree-on-the-Air with Hex-Pac

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-10-21 13:28:32 UTC
From: James Olson
Topic: 1711 Message: 1711

We had a great weekend participating in the 46th annual Jamboree-on-the-Air International Scouting event. Boy Scout Troop 405 from Powder Springs, Georgia, hosted our Cub Scout Pack 702 station at the Kennesaw Mountain Battlefield Park. We were on the air with battery power for 7 hours with a FT897 and Hex-Pac portable @ 30 feet.

If you've ever given a demonstration of ham radio to the public, you know that calling stations with no response is not impressive to your guests. But the Hex-Pac came through like a champ! We had a 1 hour long qso with a GX0SCR to the delight of all present at the time. Over the course of the day we talked to Scout groups in England, the Netherlands, Belgium, Slovenia, and 7 different states.

The portability of the antenna and mast is terrific. This is now the 3rd Scouting event that we've used the Hex-Pac at, and look forward to future adventures.

James Olson, W4JO
Powder Springs, GA

From: wa4znj
Topic: 1706 Message: 1712

I would agree that the Hex-Beam is an excellent antenna. Although I do not own one, I have worked many on the air. When I was looking for a small antenna, I really considered this antenna, but I did not purchase it because of the price. I made a list of all the small beams including the TGM Hybrid Quad, CC MA5B, Force 12 C3SS, Lighting Bolt 2 element Quad, Tennadyne T6 Log Periodic, and CC A3S. I checked the opinions on eHam, and spoke to hams who use these antennas. Most hams loved the antenna they were using, but I was able to rule out some of the antenna due to the size of my lot. After considering my space for an antenna, I narrowed my list to the Hex-Beam, MA5B, and the TGM Hybrid Quad. Since I wanted gain on 17 meters, this left the Hex-Beam and the Hybrid Quad. I really wanted the Hex-Beam, but I could not justify paying $900 for a 2 element beam.
I think Mike has a good product, but he has priced it out of the market for the average ham. I have spoken to many people who would have purchased a Hex-Beam, but they were turned off by the price.

If Mike would reduced his price to the $300-$400 range, I am sure he would triple his sales IMHO. With the economy in a slump, hams are not going to fork over that kind of money for an antenna. I know he has sold over 300 of these antenna since he introduced them, but with a little marketing and a major price cut, his sales number could be approaching 1000 in a year's time.

So how is my TGM Hybrid Quad antenna working? Well so far, I have worked 202 countries on SSB and PSK31 in the last 1.5 years, and I saved $600 by not buying the Hex-Beam. Although the Hex-Beam may perform slightly better than my Quad, I am satified with my choice. I may not break every pileup, but I usually get the contact.

Jeff

From: Eric Carling
Topic: 1706 Message: 1713

Being that this is a Hexbeam Reflector and not a TGM Reflector, and I would not dream of writing a such a message to it if there were one, you should accept the following repudiation.

You are overlooking several salient points. First, your Hybrid Quad is not a once in a lifetime purchase unlike a Hexbeam. Users' reports indicate substantial wear which begins to show in the 3 to 5 year period. Yours may suffer similarly to include electrical breakdown of the coils and mechanical breakdown of the rear quad section. Long term you will not be thinking it was cheaper than a hexbeam.

Secondly, a tripling of sales is probably not top of Mike's list of priorities. I would hazard a guess that illustrious position goes to making a profit. We don't know the costs involved per antenna but you don't need a calculator to figure 3x a loss = a big loss.

So its patently incorrect to state that you saved $600 when in fact in the next 10 years you will have cost yourself money. It is incorrect to state that the Hexbeam may be a little better than your TGM when in fact it is better now and its going to be a whole lot better 3 years from now. The only thing you got right is that you're satisfied with it.

Eric.

1714. Just a comment

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-10-21 18:53:40 UTC
From: Herbert Meiselman
Topic: 1714 Message: 1714

Dear All:

Although I own a Hexbeam (#188) I have been fairly "silent" on this email group. However, the very recent exchanges regarding TGM vs. Hexbeam have prompted me to offer the following comments.

Prior to owning my 5-band Hexbeam I purchased and installed the 5-band TGM. The fellow who makes/sells them was very cooperative and helpful, and I was able to contact him with ease. Nevertheless, the antenna was extremely difficult to tune and use. Lots of playing with the 4 sets of rods per band and lots of interaction between the bands. Further, the frequency range for SWR less than 2:1 was very limited. Sold it without any tears!

I am very pleased with my Hexbeam: 1) easy to install; 2) no tuning at all; 3) SWR less than 2:1 on every on SSB region of every band; 4) no evidence of changes over a 1 1/2 year period of use. Mike was fantastic to work with and was willing to help and hold my hand when I had questions. By the way, the MFJ antenna tuner that I bought to use with my TGM now functions only as a switch...dummy load for tuning the amp, then back to direct connection to Hexbeam. Thus, never use the "C and H" parts of the tuner with the Hexbeam ...only its switch.

Last comment: my wife has twice said that the Hexbeam is "not that bad looking"...a positive comment from a wife who does not deal at all with ham radio.

OK...now back into my shell.

From: NA1A
Topic: 1706 Message: 1715

I see all the points Jeff (WA4NZI) noticed about the Hex-Beam especially the cost. I agree that the price Mike wants is high when compare to others. However, let me just say this: I've had a three element Cubex quad for 10, 15, 20m up for three years back in the early 80's, then a Mosley PRO-57B up at 75 ft for two years, after that, a Force 12 C4 also up at 75ft for two years. My most recent "big gun" antenna was a 5 bander full size 2 element cubical quad by Lightning Bolt up for 2.5 years. I recently had to take it down due to neighbor complaint (and I won't go into that here). After taken down the Lightning Bolt antenna, I put up a TGM MQ-26 and kept it up at 50 ft for a two weeks. The results was mostly disappointments. I guess because I was spoiled by the Lightning Bolt.
I always keep at least one or two "reference antenna" to compare my beam with. They usually are simple dipoles, inverted-V's and/or verticals. For the last 2 years, I have been using a Carolina Windom and an R-7 as my "reference antenna". Never ever in the past that I have lost a signal by going from the beam to the "reference antenna". In all cases, whenever I heard a signal with the beam, I could still hear it with the "reference antenna". They were of course, not as strong, but never lost the signal. With the Hex-Beam, many times (not always, but often enough) when I switch to my "reference antenna (ground mounted cushcraft R-7 and Carolina Windom at 50 ft), that signal was un-detectable. It was like no one was using the frequency. When switched back to the Hex-Beam, that station was there with yacking away. I'm not talking about an S-2 or 3 signal. I am talking about decent S-6 to 7 signals on Hex-Beam and can not be heard with the "reference antenna". Until today, I'm truly convinced that my Hex-Beam outperforms my 2 element Lightning Bolt quad at 50 ft. The Lightning Bolt quad was a heck of an antenna. It was at least as good as if not better than the Force 12 C4, for sure better than the Mosley Pro-57B, and absolutely beats the TGM hands down, no questions. That was why I only kept the TGM up for two weeks...
My experience is that NOTHING, none of the above mentioned antenna yield the performance that I am getting with the Hex-Beam. Those who have talked to me through the years know my signal with various antennas that I have had. Their comments now is that they have never heard me as loud and strong. The audio is more pronounced on the Hex-Beam than with any of my previous beams.
I feel that if you really want to know the real performance of the Hex-Beam, you simply have to try it. Once you have used one, the cost of the antenna is merely a shadow in the back.
BTW, WA4ZNI or ZNJ who name is "jeff" is not a valid callsign in the FCC database.
Cheers!
Duke - NA1A

1716. Price of Hexbeam

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-10-22 02:14:07 UTC
From: Jason Hissong
Topic: 1716 Message: 1716

Good points from Eric. As far as price, think about it:

A Quad and or TGM antenna may not last long (hence the points Eric made). Also, look at the F12 antenna... it is a good antenna and guess what... it is in the same price range!!! (The 5 bander with gain on ALL 5 BANDS is the one I refer to). So, you could get a F12... but the turning radius is large AND it is heavy.

Anyways... if you are happy with your TGM, then that is a good thing. However, I think you would have been better and saved up for a Hexbeam. I still love mine... and my earlier comments about a Quad I retract as the quad would not have lasted as long as my Hexbeam.

Good point Duke. I have search tools for older calls that allow relating older calls to those having a Vanity call back till about 1990. There is no WA4ZNJ. I also directly email Jeff and have received no reply. I also note that he joined the Hex-Beam Group less than an hour before he made this post. He may have been reading the posts all along and not joined since I allow the archieves to be open to all to read. Or perhaps there is another reason behind his posting. Hope Jeff will clarify who he is or else his entire posting becomes a mystery.

Hi Barry,

I saw the threads to my post on the Hex-Beam group. As for WA4ZNJ, it is not a valid FCC callsign. I use this email address because my callsign was already in use by someone else. As for the price of the HEX-Beam being reduced to $500, I would have to agree that Mike could sell more antennas. If the the 2 element Lightning Bolt Quad can sell for $289, I do not understand why the Hex-Beam sells for 3 times that amount. I understand that Mike has marketing cost associated with this antenna, but most hams I spoke to think it is an excellent antenna, but the price of ownership is TOO HIGH.

Jeff

> associated with this antenna, but most hams I spoke to think it is
> an excellent antenna, but the price of ownership is TOO HIGH.

the answer to your question can be found in the amount of manual processes used during manufacture and the amount of handholding Mike gives to amateurs after the sale. For example, a hex beam has 10 pieces of wire with four measured segments each. There are four loops formed in the wire at each point. Each of the spars must have six attachment points (1 for each band plus the top strain relief rope). The base plate has numerous holes of different sizes as well as a mounting point for the antenna mast (welded?). Then if I understand the advertising correctly, the whole thing is assembled, tested and then disassembled, packaged and shipped. If you looked for fingerprints from Mike and his staff, they would probably be three or four deep on all of the components.

from an RF perspective, the hex beam sounds like a wonderful little antenna. However, from a manufacturing perspective it is probably a nightmare. The only way Mike could make them significantly cheaper is to farm out the manufacturing to some little slave labor camp in China and I hope he has enough integrity to not do so.

Now it is possible to reduce costs manufacture through clever designs and processes but it might not be practical to do so until the volume gets up. For example, one could use special fittings and clamps to attach the wire to the spars. One could use painted on markers for assembly indicators. But all of these require a certain degree of volume before it becomes cost-effective.

Now I just went to the hex beam site to verify a few things before I spouted off and it looks like he's trying to explain/justify/compare costs. And I think he's doing a good job. He also has a 40 m version (ooh mama) with the 19 foot turning radius which probably means the 80 m version would be slightly smaller than my house is long. Heaven help the neighbors.

I am going to try and build myself a clone just so I can get a feel for how this type of antenna works. I must admit to being torn between the steppir and the hexbeam. Both have their advantages and disadvantages. But I'm sure whichever one I get will be just marvie and provide many years of enjoyment.

From: dl7io
Topic: 1720 Message: 1722

Hello,
regarding this discussion I would like to give Mike a helping hand.
Another reason for the high price/costs is that the spreaders Mike is using are much, much more expensive. They are conical and not like a tube.
I meanwhile build a couple of beams myself and use also custom made conical spreaders instead of combined tubes like most homebrewers do.
And only the spreaders costs more in the purchasing process than the whole quad in the sales.
Those conical spreaders should be used to get the antenna into the right shape.
And as somebody already said before there is much more handwork on this beam. The ones that tried to build this antenna may have an idea of the needed time to get on beam ready. Even if you are more experienced with the process it takes about a whole day per antenna and 1 man. And if this is his job, he of course needs some earnings out of this. And the only money he can take of of the price are his earnings. I'm sure he can't sell that many antennas more for less to make the same money. If you are cutting your marging (not the price) by half you need to sell twice as much to have the same money left...
regards Holger, DL7IO
PS. Moved to the new home now and installed my beam on the roof first (9m) to be back on the bands. Because it is already cold here (minus degrees!) I have to delay building the towers to the spring. But I started modelling a multiband version for 40m and up.

I know of a HX5B in Germany that is for sale. The HAM build a 3/4
element quad and replaced the Hexbeam with it.
It is a seriell number in the 40's or 50's.

Look at the website from EI7BA..He describes a 5 band homebrew Hexbeam.
http://www.qsl.net/ei7ba/
Also have a good look at the Photo section in the NG..
Like VE7ASK and John PA2JJB who has recently started building one..
Read some of the posts in the message section,there is alot of info there.

1736. HX5Bi on other bands

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-10-31 00:17:56 UTC
From: t_ashland
Topic: 1736 Message: 1736

Hi,
I really love my hex! With that said, I am wondering if others have loaded their hexes on 30 or 40? I am using at FT-1000MP and it doesn't quite load up very well with the auto-tuner on 30 for me.
Has anyone used like the LDG tuner with them on the other bands?
Thanks and 73,
Terry, WK0F

1737. 6m Aurora!!

> Thanks and 73,
> Terry, WK0F

Hi Terry,

Using the tuner in my 1000MP is iffy on 30 and 40 m. Shifting freq
by just 10 kHz can make the difference.

I now use a LDG AT-1000 autotuner with my VL-1000 amp. Now it tunes
the Hex-Beam on 6-80 m FB. I have used the VL-1000 on 40 m a few
times, but limit the power to a couple of hundred watts since I (nor
Traffie) have any idea of the power capability in this case. I would
be VERY sad if I harmed my beloved HX-5B. ;-)

I hope to improve my 40 m situation soon with the addition of a 40 m
Hex-Beam and join the ranks of just a handfull of 40 m HB owners. :-
)))

I also have used the LDG AT-11MP and LDG RT-11 autotuners with the
1000MP to operate on 6, 30, 40 , and 80 m. I like the 11MP best for
this application, but it doesn't cover 6 m so well, while the RT-11
does.

73,
Barry - W4WB

From: P. Buijserd
Topic: 1737 Message: 1739

hello all,
yes, aurora was great last night. I own a HXL-1510 and have added wires for 6 meters myself. Working ok, low SWR and yesterday's conditions brought some good dx, including a new dxcc for me: GJ Jersey. Really pleased with that one, 'cause so far I worked about 85 countries on 6, and finding new ones in Europe isn't easy.
Also I could work an Italian station, really rare on 50 MHz aurora, and I heard a YU, but couldn't complete the contact.
By the way, I also worked stations on 2 meters, and heard some strong stations on 10, also fully auroral.
As a big bonus, I was able to watch my first visual aurora, really beautiful fireworks !

1742. New pics in photomap PA2JJB

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-11-03 21:24:18 UTC
From: PA2JJB
Topic: 1742 Message: 1742

Hello everyone,
Last week I make a RF-choke on a T200 toroid and put
in in a watertight-case with 2 N-type connectors. At me job PH0DX and
I tested it on a network-analyser and gives a good curve from 10 - 40
Mc and SWR < 1,2. So very interested what this thing will do in the
real world with the HEX-beam.
Saturday I buyed 40M = 33 feet twinwire gauge 14 (I think) and
measured all the driven and reflected elements. I used the dimensions
of DL7IO and put marks on the places that are 10cm shorter then for
bare copper wire.Also put a mark on the wires for velocity-factor
from LZ2?? = 0,954, and we will see what the real lenght will be,
when I trim my HEX-beam with my antenna-analyser.

One quistion from my side:
What is the best way to trim this baby??
Put all the wires in place on the centerhub and bamboo's and then
start trimming first 20M and so on. Or first connect only the 20M
dipole and reflector; trim it to the wanted frequency and then after
that connect the 17M dipole and reflector trim it and so and so on!!!!

Hope the weather will be my friend coming weekend and I can assemble
my HEX-Beam and trim it to my favourite frequencies.

Oh yes the last picture is made from 5,50M electrical housewire,
stressed it so the wire will be "dead", and stripped the isolation of
it. Took me only 15minutes, and maybe I will try also this wire on my
HEX-beam.

OK guys, as you see little by little is this project growing to a
real HEX-beam and hope I can use it in my Chrismas-holiday

Topic: 1742 Message: 1746

Hello Jan,
it is fun and interesting to follow your project step by step.
Regarding your question. You first have to install all the elements.
Otherwise you will not have a useful result. I remember that I had
all resoncences out of the bands when I used PVC-wire first time and
shorted all wires at once by about 10-15 cm (depending on the band).
From here I started the fine tuning. Usually a change of the length
of one dipole will influence the neighbour bands. Please remember
that the best SWR is not the point of best gain. The gain slows down
with the increasing frequency within the band. So if you can accept a
SWR of 1:2 or a bit more in the CW portion you will have a little bit
more gain here. I have replaced the powerpoint files by pdf's in the
file section (under DL7IO)because of the many requests I got. The
German version has a few more slides. Within are some pictures out of
EZNEC where you can see the SWR and the gain on a sample of a 15m
single band version but it is almost the same for the multiband
versions.
Be careful with the cutter knife and use straps or something like
this first!
regards Holger
PS. I have erected a 15m crank up tower last weekend. If the weather
is not to cold I will start experimenting with a multiband version
40m and up.

Hello Holger,
Thanks for your answer and gives me the idea that I'm
moving in the right direction ;-)
Downloaded ur PDF-files and they are very nice; so I printed the
German PDF and put in my HEXbeam-information-book.
Hope to bow this weekend the bamboo's and start to install the wires
and maybe I have the time to trim the wires with the AEA-antenne-
analyser. Hope we can inspire other hams to build this magnificent
antenna, and exchange more experiences!!!

1748. More Dutch hams who buy or built a HEX-Beam ???

Yahoo group: hex-beam (2001 — 2006)

From: PA2JJB
Topic: 1748 Message: 1748

Hello all,
I wonder if there are more Dutch radiohams who has build or buy this HEX-beam ??? I know PE3AA - Davy has built a 10M-HEX, and will make a 5-Band HEX. My collega PH0DX (what a call ;-)) who has built a 20M-HEX and is so enthousiatic about it; that he will built a second one for 5 bands !!! (you can see his pics in a fed days in the photosection of this group)
I saw messages with PB1TT who buyed a HEX1510 and liked it also very much. Maybe we can exchange experiences on 80 or 40M or via phone.

All lots of succes in building or many DX with this HEX-beam

Hello,
for those of you who are interested/able in calculating an EZNEC-model of a multiband beam for 30/40m with feeding from the bottom I have loaded a file into the file section under DL7IO.
I'm very interested in comments regarding this.
thank's for attention and have a nice weekend,
Holger

Tnx Holger. I have one question. Why is the 30 m elements on one side not in the plane with the other side and parallel with the 40 m elements?

I am particularly interested in this since I hope to have a 40 m HB from Traffie in the near future. It is my understand that he attempted to make a 30-40 m HB in the past and found that, although it would work, the performance of the 40 m beam suffered more than acceptable from its mono-band performance. I would, of course, desire to have 30-40 m capability, but not at the suffering of 40 m performance.

I look forward to your reply.

Hello to all,
Today I have worked on the bending of the bamboos and
that was not so easy, because my garden don't have enough room to fit
the HEX-beam ok. PH0DX used a different manner to bend the bamboos
and it worked very good and easy!!! When the weather is good tomorrow
I will try to fit the wires in this nice antenna-project.

Hello Barry,
sorry for the delay. I have been in Spain and Finland during the last week and used the evenings in the hotels to calculate the model of the beam. And coming home for the weekend I spent the time with Birgit and the kids and not on the computer.
I also found those 2 hanging wings and changed it but the influence is minimal. I continued the optimisation of the beam and came to a bit better SWR on 40m (1:1,3 at 7,05 MHz). The shortening of the endisolators or the 40m elements brought the decrease of the SWR. They now are shorter than for 30m. This was somehow suprising to me and I'm still trying to interprete this. I will change the files and add the excel file with the calculation for the XYZ-coordinates. Than everybody can continue to work with this model. The gain on 40m is about 6,x dBi (free space, no losses) which is almost the same like for monoband or other multiband versions. I think 30m is a bit less but take that beam to 15m height and look on the TOA and I see no problems entering in DX-pile ups. I'm thinking what spreaders I should take?

I don't know what Traffie was trying/calculating but I'm sure he also uses some software to calculate the model first and as long as there is no self optimisation routine implemented it is a hard and long way to find the best solution trying it out by changing some lenghts in cm steps... Probably he has some internet connection now and is willing to take a look on our first proposal. It would be a great honour for me to listen to his comment
regards Holger

Most understandable Holger. I look forwarded to your revised design. Traffie told me that the 30-40 m HB worked, but not as well as he wanted. Seems that the gain is okay, but the F/B is degraded a bit.

My 5Bi loads easily on 6m with the 756Pro internal tuner. Neither
that inernal tuner nor the MP Mark V's will load it on 30m or lower.
However, my Palstar AT1500CV loads it down to 75m (haven't tried it
on 80m or 160m). I admit taht I just loaded in on the lower bands for
grins and I kept the power down to 100 watts. My "normal" 40m antenna
is a Force 12 vetical dipole and the hex (here's a non-surprise) is
not as effecient.

Good Morning; My 5 HBi loads op on 40 and 80 quite well with my Kenwood TS930SAT, however my center fed Zepp out performs it by a least 2 S units on both bands (Off the sides of the antenna). I have used it (the HB) on the 40M SSTV net wiith some success. My IC 706 tuner will not load up the HB on these bands. All the best Ralph WA2NTK

From: k4pzc
Topic: 1757 Message: 1757

Hi to all. This is my irst post. Hope someone can help. I've built a 5 band Hexbeam from DL7IO's file and it tunedup very well. I then put a RCS-4 coax switch inline with it at the base of the 30ft pole it's on and the swr went from 1.8 on 20m to over 9. The other bands are even worse. I called Ameritron and they don't know what is wrong. Anyone else have this problem or know how to fix it?
Thanks

Sandy K4PZC

From: E8N2CG@aol.com
Topic: 1757 Message: 1758

Hi Sandy,

I believe the problem with your high SWR measurement is not the fault of the 5 band Hexbeam nor the RCS-4 coax switch. I'm guessing you initially checked the SWR of the Hexbeam directly to a Wattmeter with no other antennas being connected to a common ground coax switch and measured 1.8:1 SWR. Then you placed the RCS-4 coax switch and perhaps connected some other antennas to this switch. If this is so, one of the coax leads may be causing your high SWR problem. Try removing all antennas (disconnect one at a time to find which one is interacting with the Hexbeam) from the coax except for the Hexbeam and see if your SWR goes back to 1.8:1. If you have a ground wire on the coax switch, try disconnecting it as well to see if that is interacting with the Hexbeam

Kindly advise us of your findings.

73,

George N2CG

1762. Homebrew Hex Bitz idea`s in UK.. and beyond

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-11-24 11:54:50 UTC
From: Colin
Topic: 1762 Message: 1762

Hi all,
Here`s a few idea`s for homebrewers, mainly in the UK, but may help others with the hub idea.

An easy method for the hub assembly is to locate a Kee Klamp supplier (they have branches in France,Germany,also Buffalo and Ontario) (http://www.keeklamp.co.uk)
They have a range called "Kee-Lite" which is a hardwearing cast magnesium/aluminium lightweight alloy.
The 4 bolt square flange fitting costs about £6 here in the uk and will accept upto a 43.2mm dia tube.
These make for an easy professional looking hub that should last almost forever,simply use 2 of them and 4 x 10mm bolts to sandwich a 0.25" aluminium plate.
They go upto about 63mm dia and also have circular plated versions.

Also for UK hex homebrewers,a supplier of fibreglass tube at reasonable prices is RBJ Reinforced Plastics Ltd (Hertfordshire) (http://www.rbjplastics.com/index.htm)

For 5 band Hexbeam spreaders: (nice sliding fit)
2 x 5mtr lengths of 19mm x 3.2mm wall
2 x 5mtr lengths of 12mm x 2.25mm wall
Cost inclusive of V.A.T & overnight delivery: £51.23 approx.

Each spreader (comprising: 1666mm x 19mm + 1666mm x 12mm) weighs 0.7kg (assuming the wife`s kitchen scale is accurate)
They are a thousand times stronger than telescopic fishing poles,and have the perfect amount of bend.
You can have any colour you like as long as it`s white ;)

Nevada Radio (http://www.nevadaradio.co.uk)
#14 swg Flexweave copper wire is £40 for 100m drum (so you`ll have about 19m to spare)
They also do 2mm black Dacron line.

You should be able to build a long lasting 5-band hexbeam to be proud of..for about £120-£150.
(stainless steel u-bolts and hose clamps are expensive wherever you look)

I hope this info is useful to someone
Have fun with the Homebrewing
Best Regards
Colin

1763. Some delay in my postings and pics

Hello to all of you,
Try to sent this message for the 3th time !!
Its a while ago I post my mail and pics, that has two reasons: my wife and I become grandma and grandad for the 3th time, and on our way to see this new QRPP Sam, our car was hit from behind, and was totalloss....we had for a week a very stiff neck and back, but after all we are in good health again.
Two weeks ago I try to install my first dipole (20M) and all went wrong....I put to much tension on it and the PVC-pipe bow like a bamboo !!! I let all the bamboos back horizontal, and make a aligntool (see pic) (thanks to davy PE3AA for the hints) so I could align every bamboo for the same lenght.
A week later I put the aligntool on the PVC-pipe and it was possible to align all the bamboos within the cm. After that I started to install all the dipoles and they are all almost in there place on the bamboos. The next day I should install the reflectors but my grandson was more important that moment....
So weather was last weekend terrible here, and nothing could be done to go any further with the HEX. So lets hope next weekend will be better, so I can finish all the wiring and align the wires on the bamboos and hope to do some measurments with the AEA Matching-Analyser.

Best 73's and good luck with the HEX-Beam.

de Jan PA2JJB

Please tell how did the PVC preformed (at least during
assembly)...I've plaaned building the HB, but stopped due to my
inability to find proper spreader material.
At first, I was intending to use PVC pipe, but was adviced against.
Then I start thinking fiberglass rods, but foud them way too
expensive, at last I researched telescoping fishing rods. Their price
was OK, but it was hard to find the proper lenght.

look at http://hamstuff.blogspot.com for details of the adventure.

Hello Paulo,
I used bamboo for the spreaders !!! I make from a PVC-cap of 40mm the aligntool (see my pics in the map PA2JJB.)
Trough the cap i put a 6mm (1/4ïnch) bolt with 6 cableshoes.....true each cableshoe I put a nylonwire from about 281cm lengt and the other end goes to the endtip of the bamboo-spreader.

By the way we had our safetybelts on, because otherwise I never was be able to type this message to you lolll !!

Good luck and best 73's from Jan PA2JJB

1766. Homebrew 5 Band Hex

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-11-28 06:43:47 UTC
From: gfarek
Topic: 1766 Message: 1766

I have built a 5 band hex recently and have a good vswr on all bands, 1.2 to 1.8 in the General phone freqs. My question is, does anyone have any idea of the proper feedline profile. I used a 2" fiberglas center pole with the prescribed spacing and stainless bolta and 1/8" stainless rod attached inside the tube to all band connections. It seemed to match up on the first try. Will try to send pictures at a latter date. I would like to hear of other feedline mechanisms.
Thanks, Jerry

1768. My HEX-Beam ready for testing

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-12-07 19:14:09 UTC
From: PA2JJB
Topic: 1768 Message: 1768

Hello to you all,
Today I finished all the wiring of the HEX-beam and
the wires are almost on their right places on the bamboos. On advice
of Holger DL7IO I make all the wires of driven and reflector elements
10cm shorter, because I'm using isolated wires, but keeping the
lenght of the endwires for the driven and reflector elements
unchanged. I connected about 70 feet of coax to the beam and put on
my IC-706 and the SWR's on all bands where not bad at all, but the
beam was only 3 feet above the ground....I hear LZ2TU calling CQ on
18.071 Kc and answered him with only 20Watts and he come back for me;
so that was my big thrill !!!!!
The beam works only 3 feet above the ground and works some more
stations in Spain and Russia all with 20Watts.
After that I put the beam on a 10 feet mast and saw the difference in
SWR now, but its on all bands below 1:2....not bad at all.
Heared some W-stations on 15M just before the bands closing and I
think the HEX-beam is very quiet to listen.
Tomorrow I will see with the AEA-antenna-analyser what the SWR-curve
and resonance really is doing at this height.

Best 73's and good luck by building this amazing beam.

Hello John.
Always nice to see that you are progressing so nicely with your
Hex-beam.
It has become too cold here to do any serious antenna work.
The temperature is mostly below zero degrees celcius and there is
snow on the ground too..
Hope that the weather on your side of the pond stays good enough to
hoist your antenna up in the air soon.
PS: did you get my E-mail dated Oct 13? If not I will send it again.

Hello Sieb,
Thanks for mail....no I did'nt receive your mail of oct
13. At a hight of 10 feet all resonance-freqencies are below the
bands. When I come home from my job its dark to do anything to prune
the beam. Also freezing here at the moment, but temperature will
increase during the week and I hope to tune the HEX-beam in the
coming weekend.

Hello Holger,
My HEX-beam is almost ready to tune and put it on my roof b4 the PACC-contest !!!
Busy making a programm for calculating the beam in ACCESS2000.
Wonder what formulas you have used to come to the dimensions f your beam??
Must run now for my job !!!!

Hello Jan,
it is fun and interesting to follow your project step by step.
Regarding your question. You first have to install all the elements.
Otherwise you will not have a useful result. I remember that I had
all resoncences out of the bands when I used PVC-wire first time and
shorted all wires at once by about 10-15 cm (depending on the band).
From here I started the fine tuning. Usually a change of the length
of one dipole will influence the neighbour bands. Please remember
that the best SWR is not the point of best gain. The gain slows down
with the increasing frequency within the band. So if you can accept a
SWR of 1:2 or a bit more in the CW portion you will have a little bit
more gain here. I have replaced the powerpoint files by pdf's in the
file section (under DL7IO)because of the many requests I got. The
German version has a few more slides. Within are some pictures out of
EZNEC where you can see the SWR and the gain on a sample of a 15m
single band version but it is almost the same for the multiband
versions.
Be careful with the cutter knife and use straps or something like
this first!
regards Holger
PS. I have erected a 15m crank up tower last weekend. If the weather
is not to cold I will start experimenting with a multiband version
40m and up.

The resonant frequency will increase signficantly as you raise the
antenna. Beware trimming at low heights.

From: PA2JJB
Topic: 1773 Message: 1773

Hello to you all,
Does anyone know how much the frequency will
increase when I move my HEX-beam from 10 feet to almost 33 feet above
the ground ??? These are my values measured with the AEA-antenna-
analyser but near my house and WARC-band-dipoles near the HEX-beam
(see pic in my photomap PA2JJB.)

20M
13.500 KHz 1:3
13.575 1:2
13.640 1:1,6

17M
17.580 1:3
17.740 1:2
17.850 1:1,7

15M
20.580 1:3
20.700 1:2
20.850 1:1,6

12M
24.400 1:2,5
24.700 1:2
24>850 1:1,8

10M
27.600 1:2,7
28.250 1:2,2
28.400 1:2,2

Thanks for answer and explaining if anyone can help me.

Jan,

As I recall, the steep increase of SWR vs. frequency for my HX-5B at about 8 feet was about 13.5 or 13.6 MHz for the 20 m beam. When it was installed at 35 feet, the point moved to just a bit about 14.0 MHz.

From: k1mzg
Topic: 1776 Message: 1776

Hi all,

Just uploaded some pictures of my hexbeam installation. It is the
5 band version on top of 30 foot mast, both from Mike Traffie.

I took Mike's advice and installed the Radio Shack TV rotator, at the
bottom of the mast, about 2 feet off the ground. Also, the guy lines
are non-inductive 5/16" dacron line that supposed to be UV resistant.
I got the the dacron line from http://www.davisrf.com/. The anchors
were obtained from a local garden supply store.

The bottom of the atenna is at 32 feet. I have a pretty flat location
at 950 feet above sea level. Works great! Spend most of my air time on
17m. On 12/7 we had 5 hexbeamers on 18130. Quite a convention - seems
like hexbeams communicate well with each other!

CU on the air. 73's

Hello to you all HEX-Beam-enjoyers.
I placed a pic in my photomap
(Look for the last one) PA2JJB and ask you what is the best place to put my HEX-BEAM. Wonder if my roof will have much influence at that hight (38 feet)My chimney is very strong build and when I put a aluminium pipe from about 9 feet, that is the easyest way to achieve the highest place for the HEX-beam.
Will make today some pics near the chimney so you can see it by yourself what is possible.

For now Merry Chrismas and a happy New Year 2004

What matters mostly is what is inside the roof that is metal. If you can get the 20 m elements at about 42 feet, that would be great. I expect that you will be fine doing what you suggested. Nice slope on the roof!

BTW, please remove some of the photos after you have finished the project and keep it to just those that are actually needed. We are running out of space. Thanks.

Hello Jan,

I had to make such a decision a year ago and I decided to put it on the top of the roof, near the chimney. It is about 2m above the roof. You can see how it looks in Photos session LZ2BE. I would suggest to put your Hex near the chimney at the left side of photo. Your roof slope is higher than my house, so Safety First! Think about how you will have access to the beam, if it needs some repairment later.

Hello Barry,
Thanks for the info and I will fix the mast to my chimney.
There's only wood under my roof and nothing else. My 40-20-10M
dipoles are also hanging a few meters above the roof; thats is the
half of the dipoles, and working fb for many years now.
They will be removed when the HEX-beam is in his place.

I think the chimney is the place to go if it is strong enough.

Your next project needs to be creating a web site with all those photos. It's to bad there is not much room on this one.

1783. Left the important pics in my map ! And placed 2 new ones.

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-12-18 18:44:14 UTC

Hi Tom,

Long time no hear! I have a HX-5Bi and if you search through the archives, I think you will find input from folks using the Traffie masts with Hexs at about 30 feet. Mine is at 30 feet on an old Triex 37-TC.
Some of us bought the 10/15 meter Hex and sent it to P5/4L4FN when Ed was in North Korea. I have seen some of the DXpeditions using Hexs also.
Let me know if you would like to test drive the HX-5Bi. I now have a FT-1000MP as the main rig.

Topic: 1787 Message: 1789

Tom,

I've been using the HX5Bi and the HDX-30 as a "temporary" fixed configuration at my home qth for nearly 3 years. The HDX-30 is pricey, but the quality appears to be outstanding. I purchased the anodized bronze mast as it blends in with the trees quite nicely. The mast telescopes nicely, although a little WD-40 sprayed in each of the mast sections when I re-extend them (I check the antenna every six months or so)makes it go a bit easier. The two sets of guy rings also appear to be high quality and allow the mast and antenna to rotate freely.

Not sure how the HDX-30 compares with other telescoping masts, but the weight seems reasonable at 20lbs. The built-in locking pins are good and the heavy duty push-in pins seems solid.

I recall the HDX-30 comes with two antenna to mast sections: (a) short piece under a foot that will basically take the mast/antenna to a bit under 30 feet, and at 30 feet at the 20m element, and (b) a 5 foot piece which will get you higher. I elected to go with the short piece as the weight and mass of the HX5Bi and the 5 foot section attached to the HDX-30 was a unweildy even for 2 of us to put up the first time. Note that my mast and antenna are mounted ON a ground mounted Yaesu G-1000DXA rotator..the rotator turns mast and antenna. Hence getting everything set up the first time is definitely a two, if not three, person job.

The mast is guyed at 2 levels with 3 guys each. I use 5/16" double braid rope, although I suspect 3/16" would work fine. The guys are held tight using "rope pulls" (you can get them at RadioWorks or Home Depot). The rope pulls are then attached to stakes or dog-run screws I put in the ground.

20m performance is very good at this height..actually the antenna performs well on all bands. No regrets and would do this again if necessary.

Hope this helps.

Topic: 1787 Message: 1790

My experience and set up are very similar to Harry WE1X's. I have been very satisfied with it and consider it a permanent installation.

Like Harry, I lower the sections of the mast about every six months and use the trusted WD-40. I live in a very windy area (there are wind farms just down the road) and the mast has held up well.

As for the performance of the HX-5Bi -- I have been very happy with the way it plays on all bands. I dream about a tower, but the only new antenna that I would put on top would be a 40 meter beam. The HX-5Bi would stay!

If you have any questions, please feel free to contact me.

1792. Hex Beam for Sale (5 Band)

Date: 2003-12-25 23:12:24 UTC
From: Marty N5NW
Topic: 1591 Message: 1792

I have acquired an HX5B, very good condition, currently disassembled. I have all the hardware. S/N is 073. I plan on moving in the next couple of years and don't want to hassle with it. Also, have a 40 ft aluminum tower on the ground, no hardware or base plate. Very light, perfect for the Hex. 5- 8ft sections, taper in the middle, top section included.

I'd like $900 for the package. I can't ship the tower -- I live in the SE Suburbs of Dayton, Ohio. Separated, I'd sell the antenna for US$650 and the tower for US$350. I'll give it a couple of weeks to see if anyone wants to buy the package, then I'll separate.

All costs plus actual packing and shipping.

Would consider trade for excellent condition Yaesu FT-847 with the Collins CW filter.

1794. Anybody feed a monobander from a tuner for multiband op?

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-12-30 02:15:32 UTC
From: yahglabelle
Topic: 1794 Message: 1794

I'm looking at the HexBeam. Other choices are the Cushcraft MA5B (almost eliminated due to poorer performance) and the TGM "hybrid" quad (nearly eliminated due to narrow bandwidth, tuning and reliability issues). I need a lightweight antenna that can be turned by a TV rotor and mounted on a smallish roof tower due to XYL constraints :-)

I'd like some gain. My other strong contender would be a rotatable dipole - disadvantage, no gain - advantage, all band operation, fed from a balanced tuner. I'd like to know if a monoband HexBeam (say 30 or 20M version) could be fed with ladder line and worked from resonance and up (and maybe down?). Anyone tried this? Sure, I could get the 5 band antenna to begin with, but I already have a good balanced tuner, and a monobander would be smaller, lighter and less "obvious" (and cheaper!).

Thanks,
George

In my opinion, you would be sorely disappointed if you did what you propose. You may derive nearly the design characteristics of the beam on the primary band. Operation on the bands above the design frequency would be similiar to using a doublet and have minimal directional benefits. Characteristics will vary from band to band. Perhaps some of the other reflector members have modeled something similar and can present some finite data.

George,

I would think the main problem you would have with using pen line and a balanced tuner would be the reflector element, which would also need to be tuned. Therefore you would need 2 feed-lines and 2 tuners..

Of the commercially available small beams the Hex would have to be most robust and suitable for a small rotator due to it's low weight, small turning radius and being symmetrical. I can't comment on the gain of the others, but the Hex is OK, although 10/12 metres is not so good. I never heard a good report on the TGM antenna, but know a few people with the MA5B, who have good things to say about it. I've also heard good reports about the C3SS (can't remember who makes it ??). The main disadvantage of the Hex would have to price I suppose, although they're pretty straight forward to build.

If your determined to use open line, look at a Small Delta Loop Antennas (SDL's). These are covered in a few text books, the main one that springs to mind is "HF Antennas for All Locations", by G6XN (RSGB Books). There is also a 2 element beam version, he calls the 'Claw', which for me would have to be the Best Small Beam Antenna there is..

Then again... A simple dipole at the right height is hard to beat for ease, cost, visual impact and performance. The fact that they would be by far the most popular Amateur antenna ever has to tell you something !!

1797. thinking of HEX

Yahoo group: hex-beam (2001 — 2006)
Date: 2003-12-30 16:23:00 UTC
From: iz5diy
Topic: 1797 Message: 1797

Hi guys,

I am going to build my own Hex antenna.

I read some of your interesting message, file and watched your files and pictures.

I think I'll follow DL7IO path.

I'd like to start with a bi-band hex antenna (20 & 10 MT).

I already have my spreaders: fiberglass diameter 1,5 cm (filled inside not a tube). I found them from my "horses" electric paddock (I hope now they don't run away!!! - and my father IW5DHS run after me).

I haven't "nude" copper and I have to use insulated copper so I read into DL7IO instruction to reduce leg's lenght of 10-15 cm (but I guess it is not same for all band!). Does anyone have a measure table for insulated copper? or "experienced" measure?

Hope to read you soon and make "real" my hex antenna in first week of 2004 (finally an holiday-week for me).

Silvio

P.S.: Anyone know Italian station running with Hex antenna?

If you ran something like a remote RT11 tuner or ladderline to a 44
ft rotatable doublet you actually would have gain on certain bands.
Cebik has plans for one on his website. Just no front to back to
block noise. You could use it from 10-40 meters with no problems.
Another disadvantage would be having to tune all the time. You would
also be limited in power by your tuner. And, you would still need
something larger than a TV rotor to rotate it. You could use a tuner
on a hexbeam, however, you might as well thrown up a hunk of wire.
You will loose your gain and directivity.

With the 5 band hex you would have gain on all the bands,
directivity, pre-tuned bandwidth, and you could run the legal limit
without thinking about tuners. But, I still would not recommend using
a TV rotor.

Anyone else have any thoughts?

Hi,

I am looking for measure for insulated copper.
I read DL7IO pdf file and I think I'll send his path but I have not
"nude" copper and all measure refer to this type.

No my experience and that of others. I have seem abt 1.5 S-units
F/B on 30 m, and abt 1 on both 40 and 80 m. Gain? Who knows. Made
a number of contacts. Used various LDG tuners and kept the power to
100-200 W.

Hi,

I am quite close to purchasing or making up a hex beam. I have read almost all the mail and occasionally get conflicting reports. Recently I saw a comment that the antenna is not so good on 10 and 12 meters. Does anyone have any comments on the upper band performance and does anyone have any emprical data on its performance??

I have read that some folks have abandoned 2 element quad antennas in favor of the hex beam and I find that asonishing. My main reason for not putting up a quad is ease of supporting an antenna and in that respect the hex beam would win hands down.

Mine kicks on all 5 bands. I bust pile ups with ease and always get
good reports. In short, if I can hear them, I can work them. FWIW,
my ambient noise level is quite low. :-)

Hi Burke,

Everyone has an opinion and everyone's installations are a
little different. I have yet to see much "shootout" data although
many have modeled the Hex. Modeling is a nice tool that provides good
design data and presumes applicability. All most of us can do is cite
our own observations; some concur with modeling, some don't.
My HX-5Bi has been up at 30' since 10/01 in a suburban back yard
with various pattern destroyers such as power lines, guttering, metal
patio framing and other antennas. Some times I am told I am the
strongest signal on the band, other times not. Naturally,
propagation, number of hops, and all the other variables Mother
Nature throws in are part of the equation. Most of the time front to
back is 2 to 4 "S" units, whatever that equates to, as reported by
the station other end. This holds true for all bands including 12 and
10. Front to side reports are similar or better. Given this "deck
plate" data, I have to believe that the Hex is a beam and offers
performance at least equal to a conventional two element Yagi on five
bands. Although I have not had quads at this QTH, I have operated
them from friends' stations over the past 40 plus years. I believe
the Hex is "quieter" than Yagis I have had here and for whatever
reason seems less prone to QSB. I am not aware of any antenna of
comparable size, weight, wind load, turning radius or survivability
that offers gain on five bands and outdoes the Hex on the air. Most
full size five band antennas don't appear to me to offer enough more
operational performance to justify their installation requirements
and related costs.
Many of the Hexbeam owners are available for on the air
schedules and some offer eyeball QSOs to test drive this "umbrella on
steroids."
Sorry I can't offer hard numbers as so many would prefer. All I
can say is that I am pleased with my investment and the enjoyment it
has brought to my operating.

Hello Silvio,

I'm using insulated copper wire for my Hex. You need to make wires shorter. Multiply the lenght of
elements by 0,954 (velocity factor).

Burke,

Yes, let us know if want a QSO demo of the Hexbeam. Doug was the one that I had a QSO with that allowed me to see first hand what the hexbeam can do. I have an inverted V and my Hexbeam to do comparisons if you would like to get together for a sched.

Hi Harry,

Back in March 2001 I "temporarily" set up my newly purchased HX-5Bi Hex Beam. Prior to getting the HX-5Bi, I used end fed wire antennas with antenna tuner for operating on 80m thru 12m. On 10m I had a KLM 4 element close spaced mono band beam at 30 ft above ground level. From day one, this 10m mono band beam never had any front to back ratio performance. No matter where I pointed this beam, I heard whatever stations I was working equally regardless of the direction of the beam. This beam simply did not have any front to back performance.

I first saw the Hex Beam and met Mike Traffie and the Traffie family at the 1998 ARRL New England Division Convention in Boxboro, MA. I was very intrigued with the design of the Hex Beam, but was a bit spectacle about how this antenna would actually perform.

A couple years passed and I was getting tired of resonating the antenna tuner every time I made a band change. Additionally, all my antennas were basically fixed directional because the 10m beam was unidirectional in its performance.

All I can say is that purchasing the HX-5Bi was one of the best decisions I have made. In the past 2-3/4 years I have worked DXCC on 20m, 15 and 10m (nearly 80 countries on 12m and over 30 countries on 17m although I have not operated very much on 17m) using 100 Watts maximum power on mostly CW mode. What a pleasure it is to be able to operate the higher HF bands (20, 17, 15, 12 and 10m) with an SWR typically 1.2:1 (1.5:1 my worst case on 20m) with greatly noticeable front to back ratio (typically two S units or better) on all five bands. Additionally, the added benefit for me is that I can now make instant band changes without the need to resonate an antenna tuner. Finally, the HX-5Bi is able to handle noise significantly better then my end fed wire or 10m mono band beam antennas.

Please keep in mind that in addition to my favorable operating experiences, there are also some great physical aspects of the HX-5Bi. This antenna is relatively small and takes up very little space in addition to being very light weight. It can be set up by one person within one hour or less and only needs a small TV type antenna rotor.

In closing, I cannot justify the comments you say you heard that the HX-5Bi does not perform well on 12m and 10m bands. In my case, the HX-5Bi greatly out performs my KLM 4 element 10 mono band beam at 30 ft above ground. I have never had the luxury of having an antenna tower. All of my antennas are mounted either on the roof of my house at a maximum height of 40 ft above ground or mounted at on masts around the perimeter of my back yard at much lower heights.

Oh, by the way, I never did get around to mounting my HX-5Bi to a permanent location. I originally planned on removing the ill performing KLM 4 element

10m mono band beam and install the HX-5Bi in it's place. However, since my HX-5Bi has been performing so well I'm in no hurry to relocate it. Since March 2001 my HX-5Bi has been mounted on a 8 ft mast attached to a child's swing frame resulting with the base plate of my HX-5Bi being at a height of 12 feet (or about 4m) above ground! I'm sure any top NBA player could jump up and tough the 10m band elements without any difficulty.

My shack is on the second floor of my house and as I look out the shack window the top 20m element wires of the HX-5Bi are several feet below my shack window. Whenever I point the Hex Beam anywhere from south through west to north, the Hex Beam signals are literally going through my wood frame Cape Cod style house which is only 18 feet away from the east side of my house!

So Harry, I hope I have provided you with some insight concerning the HX-5Bi having nearly three years of personal experience with this antenna at relatively low evaluation height.

73, George N2CG

From: E8N2CG@aol.com
Topic: 1801 Message: 1810

Hi Burke K1BJS,

Kindly see my recent posting to this group. I mistakenly made my reply to Harry WE1X instead of to you.

Sorry all for any confusion. The HX-5Bi is a great antenna!

73, George N2CG

George,

think you have me confused with someone else...been using my HX5Bi for nearly 3 years..and like I said in an earlier reply.."it performs like a wild love monkey on all 5 bands". Great antenna and would buy another.

Harry WE1X

Hi Len,

I live a few miles from you in Cupertino. I have had a HX-5Bi up at my QTH for the past 2 years. It is on a 19' push-up pole on my roof. If you'd like to see it, drop me some email and we can set up a time.

I live in Santa Clara,CA and I would like to see a HexBeam.
What is a good (minimum size) self supporting mast for this antenna?
I don't have room for guy wires.

HI Folks,

We are just about out of space in the Photos Area.

If you have photos posted, please look at them and see if any can be removed now. Often, photos are timely and have short life ... others need to stay.

Your help shall be appreciated.

The main differences are the use of Phillystran for the non-element spans and the improved insulators to survive high power operation. I think these are spelled out on Mike's Web site.

1827. [hex-beam] Hex Beam for Sale (5 Band)

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-01-08 21:48:23 UTC
From: Marty N5NW
Topic: 1591 Message: 1827

I have acquired an HX5B, very good condition, currently disassembled. I have all the hardware. S/N is 073. I plan on moving in the next couple of years and don't want to hassle with it. Nobody wanted the combo beam/tower, so I'm separating. I'd sell the antenna for US$650 and the tower for US$350. The tower is aluminum, and perfect for the hex -- 5 8foot sections, taper in the middle section from an appx 12 inch base to an 8 inch top section. Tower is on the ground in Bellbrook, Ohio, a SE suburb of Dayton, Ohio. You can easily pick it up while visiting for Hamvention, if you want.

All costs plus actual packing and shipping. Can't ship the tower - sorry.

Would consider trade for excellent condition Yaesu FT-847 with the Collins CW filter.

No particular frequency. Band is narrow enough so if you tuned around, you would run into somebody with a HexBeam sometimes.

No particular frequency. Band is narrow enough so if you tuned around, you would run into somebody with a HexBeam sometimes.

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-01-12 06:34:21 UTC
From: Johnny
Topic: 1837 Message: 1837

Hi All,
I'm new to ham, only have my tech ticket, but am working on my code
and general. I'm KD7TMY and am glad i found a ham related group here.
I'll be doing a lot of learning in the near future, I hope. I live in
Tucson AZ. and have been down here to long. The temps dropped to the
40's and I about froze!! But when my XYL and I retire we will be
heading back to the frozen tundra of northern WI. (up north, hea)
About 55 miles north of Green Bay. I go by the handle of Johnny. I
look forward to getting to know some of you in the near future.
Johnny

1838. 15 mt SWR

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-01-12 15:03:48 UTC
From: iz5diy
Topic: 1838 Message: 1838

Hi,

I've got my homebrew multiband hex antenna.
I built a 20-15-10 mt triband antenna in this last days.

I used insulated copper and I follow DL7IO project plan. (I had to retouch element's lenght).

I decided to build a "pre-release" version of Hex to test it. Many little things (on construction side) could be better but I built it for a "garden" test and I need better solution for a fixed installation.

To feed antenna I used two "wide" copper (as DL7IO project). Coax start at top.

Antenna runs, very fine (compared with a windom antenna), I can see effect of directivity, signal are stronger (and less noise).
All my test was with a 8 meter high antenna.
20 meter SWR is 1:1 at 14150 and under 1.3 over the band.
15 meter SWR is from 1.3 to 2 over this band. Minimal at 21150.
10 meter SWR is from 1.4 to 2 over this band.

So things are good but should be better...
I've tried to reduce 15 meter SWR. No lenght change (minimal is at 21150), so I've moved up and down insulator distance. I didn't get really better values. So anyone can suggest me something to reduce it?

Your comment about "55 miles north go Green Bay"
cought my eye. Exactly where? My roots are in
Wausaukee. There is a Lutheran Pastor who is very
active on the live wire site
http://groups.yahoo.com/group/Live-Wire/ . He comes
up with some of the most creatively designed antennas
you've ever seen. Another site that might be helpful
to you as a new HAM is
http://groups.yahoo.com/group/HamRadioHelpGroup/ .
I see on QRZ that you retired from the Coast Guard in
'91. I retired form the Navy in '81 and am now active
in the CG aux.
Welcome aboard!

From: david.douglass@optusnet.com.au
Topic: 1840 Message: 1840

Silvio,

I'd be interested to know what SWR you have on 17M and 12M also, and whether the antenna shows Front/Back ratio on these bands??

I found that a Tri-band Moxon Rectangle also worked well on the 17/12M, with a tuner, and wonder whether a Tri-Band Hex would also work work OK on the WARC Bands.

Good luck with your trials, and I wouldn't worry too much if your SWR only reaches 2:1 on 15M..

Greetings

Lot of good information here, so, I said, said I, why not put it to use.... So far I have a plywood disk cut, drilled and waterproofed, the upper and lower mast sections ready, and the fishin' ($6 each at the flea market) poles ready to attach. Not counting the cost of the rotor (flea market?), I can't see having more than $45 into the project. Enough photos without me taking up space, (well, maybe one once I get it in the air) but just a note of thanks....

A great idea.
I know I'll buy a Hex soon. I just have to determine where to put
it. In the city or in the country. Lots of concerns about mast and
placement around trees and other problems. Lots of questions.

Look in the groups page for the home frequencies of the
already scheduled net.
I?ve never been there, since I am only able to type.

Hello, Silvio - - I found that making avery small changes of length on the reflector element resulted in noticeable changes in the SWR after I had the driven element tuned to resonance. To make quick tests of how the SWR curve and shape are affected, start by clipping and alligator clip at each insulator of the 15 m element, or wrapping a short pigtail of wire to extend it temporarliy. If this takes you in the unwanted direction for improving the SWR, then you will have to slightly shorten each reflector element. In the five-band hexes that I built (both of them) the 15 metre element seemed to be among the most critical.

By the way, you might also try moving your feedpoint to the 15 m element, and slightly retune the 10 / 20 elements. On the second hex that I built, I am feeding at the 17 m element, with very good success.

My call is EI5JF and the QTH is Cashel in county TIpperary. I have had a Hexbeam here now since last summer and am greatly impressed with it. I have the 5 band version for 10 to 20 metres and must say that it has transformed my hobby. I don't think there are any other Hexbeams in EI land and would like to hear from any other users either in EI or elsewhere to exchange thoughts and impressions on the antenna. I have the beam up at about 30 feet on the side of the Bungalow on the apex of the roof. I am new to the user group and will be happy to hear from any other converts to the beam from anywhere !! Can be emailed direct to the EI5jf@... address

I absolutely agree with VE3CWO Doug. Also watch out for interaction with other structures around the proximity of you antenna. These are a few of the answers, there are probably 100 other causes too. Note to always change you reflector length whrn you change the driven element length. 73's Jerry N5GND

1854. HEXNUTS UnNet

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-01-18 03:11:45 UTC
From: w6hb
Topic: 1854 Message: 1854

I HAVE SEEN A NUMBER OF SUGGESTIONS THAT THE HEXNUTS GET TOGETHER ON A COMMON FREQUENCY / FREQUENCIES. DURING THE BETTER SUNSPOT NUMBERS A COUPLE YEARS AGO, A NUMBER OF US WERE ABLE TO DO SO REGULARLY ON 10 METERS. THE FREQUENCIES POSTED ON THIS USER'S GROUP FRONT PAGE CONTINUE TO BE A GOOD STARTING POINT. GERRY, N5GND, AND I WILL TRY TO CONVENE / MODERATE A WEEKLY "HEXNUT PARTY" ON OUR SUNDAYS. DUE TO THE IMPACT CONTESTS HAVE ON REGULARLY SCHEDULED NETS AND SUCH, I SUGGEST WE STICK WITH THE 17 METER WARC BAND INITIALLY. AFTER THE GROUP GETS GOING ANYONE CAN QSY ANYWHERE TO CHECK OUT PROPAGATION AND TO CHASE THE ILLUSIVE HXCC WARD. THE KICKOFF SESSION WILL BE:

JANUARY 18TH ON 18.156 MHZ (+/- QRM) USB STARTING AT 2000 UTC (1200 PST, 1300 MST, 1400 CST, 1500 EST)

WE LOOK FORWARD TO SEEING YOU ON THE AIR. WE WILL BE LOOKING FOR OTHER FOLKS TO SERVE AS MODERATORS AND RELAY STATIONS AS TIME PROGRESSES. FEEL FREE TO E-MAIL GERRY OR ME WITH ANY IDEAS YOU MAY HAVE. WE ARE BOTH GOOD ON QRZ.COM. KNOWING WE HAVE MANY CW HEXNUTS ALSO, THEY MAY WANT TO SET UP SIMILAR ACTIVITIES.

From: Makoto Tanaka
Topic: 1854 Message: 1855

2000UTC is 0500JST !! It is too early to open the band between
NA and JA. I worked with KD5MXE Bob at 0006 UTC on 17meter
last weekend with Hex to Hex which was very easy QSO.
I will ask NZ7X/DU1 Marty and NH2PW Phil to join the net over
the Pacific so that can you get on the air at 2300UTC on the
same frequency as a second round net?

73, Shin - JR1NHD (wising to join the net from Far East)

1858. SUNDAY NET

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-01-18 13:15:17 UTC
From: schlott_98
Topic: 1858 Message: 1858

Hi all,

I am looking forward to the net today. I have purchased a hex beam but have not been able to erect it yet because of weather (snow) here in the Northeast. I am waiting for the snow to melt off the roof. As I am typing though its snowing again. I may have to just try it on a 10 foot pole in the yard.

1860. HexNut Partyline - GREAT Inaugural Session!

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-01-19 02:56:06 UTC
From: w6hb
Topic: 1860 Message: 1860

Thanks to all who checked in on today's 1st "HexNut Partyline" that started at 2000 UTC on 18.156 MHZ. By my count, we had 8 Hexbeams in service and a total of approximately 20 checkins. Many folks queried us on the Hex, some had never heard about them and a few are waiting for the weather to break to order or install one. The inauguration of the Asia-Pacific session will be Saturday January 24th at 2300 UTC on 18.156 MHZ. Let's keep up the momentum! See you next weekend -- same Hex times, same Hex frequencies.

73 - Doug - W6HB

1864. SWR: feeding point

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-01-19 08:56:30 UTC
From: iz5diy
Topic: 1864 Message: 1864

In this last week-end (between rain and snow...) I tried to change feeding point. I move from top (20 mt) to 15 mt and now 21 MHz and 28 MHz are better but 14 MHz had more SWR. So the problem comes mainly from feeding line. I used two copper of 4mm2 size but now I'll go to change them with a 6mm2 one and one will be ensulated the other nude (like DL7IO).

Tnx to all for previous information.

Silvio

1865. 40 mt?

1866. FIRST PARTY LINE AND TOROID QUESTION

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-01-19 13:30:41 UTC
From: schlott_98
Topic: 1866 Message: 1866

Hi everyone,

Enjoyed the first roundtable on 18,156. yesterday. After the signed I tried to locate an amidon part# 77-1024 toroid. (mix 77) I could not find this anywhere on the amidon web sight. I downloaded the entire toroid list from them. I see several mix 77 toroids in the list. I understand that Barry installed them on this coax.

We still have a lot of snow here but I am determined to erect my new Hex Beam this week. By the way, Radio Shack no longer lists their 36 foot telescoping mast any longer, but I found a local dealer who still has three of them at a closeout price ($50.)

Hello Silvio,

I used the shielding of a RG214, flatten it and you have an verry
low impedance conductor..
I issolated one side with heat shrink tube ala DL7IO,

SWR on 15 and 10 meters went down a lot,

73's de Lourens,

PH0DX,

Traffie is building a 40 m HB for me that is optimized for the CW portion of the band. Hope to get it once the wx gets good enough for him to tune it up! Next task will be to install it here.

Hello to you all,
Last Sunday I installed my home made Hex, and tested it.
Results are Vy good, meaning swr on all bands abt 1.1 exept 1.5 for 15 meter band. Impedance is varying between 45 and 50 Ohm on all bands.
Finaly, indeed, now i can hear signals witch i could not hear with FD4 wire antenna before.
It even works fine on 40 meters as well, only thing is you need an antenna-tuner and front-back-ratio is not good on 40 meters as on all other bands alldow it makes the band more silent.
For Foto's you can look in the FOTOFOLDER, pse comments!!!

1871. Diameter of the 5 band hex

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-01-21 03:21:33 UTC
From: SJD N6RRV
Topic: 1871 Message: 1871

I need to know what the diameter of the 5 band hex is in the set up configuration....i know if you lay out the 5 spokes on the ground, the diameter will be about 18 feet per the specs, however, there is a 48 inch of bending upward on each spoke to tie up the wires.....given this, the diameter will be shortened.....but how much? .....has anyone done the math or actually measured it. thx

Checkout www.hexbeam.com
They have a size comparison that says the HX5bi 5 Band Hex is 9.4 feet radius, or 18.8 feet in diameter in the operating mode. My homebuilt 5 Band is about 20 feet in diameter in the operating position, but that is because I wanted room to experiment. 73's Hope this helps your decision. Jerry N5GND

1874. NEW INSTALLATION

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-01-21 12:48:45 UTC
From: schlott_98
Topic: 1874 Message: 1874

Hi to all,

Well yesterday although cold in Connecticut it was quite sunny. I managed to put the 5bi together and mount it on a mast. It is 15 feeet above the ground without a rotor. I will put the rotor on today. So far swr's are all between 1.0 and 1.2 except for 17 meters where it is 1.4 to 1. Now how does it play?? So far I have only had a few hours to play with it and made a few contacts. My references for comparason are an 80 meter dipole with a tuner for 20-15-12-10 meters. For 17 meters I have a 3 half wavelenth dipole (w5GI design) This is basically a wire antenna with the horizontal made up of wire and coax. On 17 meters my "special" dipole seems to be outperforming the hex beam by about 2 s units. On the other bands, the hex is far superior to the 80 meter dipole. These observations are preliminary and I will know more when I mount the rotor.

Regards,

Burke K1BJS

1877. NEW INSTALLATION

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-01-23 15:12:00 UTC
From: schlott_98
Topic: 1874 Message: 1877

Good morning to all,

Yesterday I got as much ice and snow off my roof here in Ct. and finally got my new 5bi up and running. It is about 5 feet above the peak of the house using a chimney mount. That puts it about 35 feet above the ground immediately surrounding the house. Our home sits on a hill looking down on our street. To the East,South and West the antenna looks at a height of around 60 feet due to the steep slope of our lot.

So far the results have been most gratifing. On 17 I compare it to my 3 half wavelength W5GI collinear dipole. On all the other bands I use an 80 meter dipole with a tuner. The antenna on 17 is about 2 units better than the W5GI. The only other band that I have any comparason so far is 20 meters where it is incredibly better than my 80 meter dipole.

The antenna is showing an average swr of 1.2 to one on all bands except 17 meters where in the middle of the band around 18.140 the swr is 1.4... The lowest swr shown is at 18.230 using the mfj analyzer in the basic mode. Here it is 1.2 to one... Now when I use the advanced mode of the mfj.. zero reactance, which supposedly the resonant point of the antenna, it shows resonance at 18.130... I am going to try changing the length of the feedline and if that does nothing I will try the ferrite beads when they arrive.

More to follow.

Hello Group
Does any other Hex user have problems with Ice and SWR problems. I got the beam in the summer and it has been working very well for me and I am very impressed with it.. Today I went to go on air and the SWR was up on all bands.... I went out and looked up at the antenna and can see ice coming down the feeder where it loops up from the Rotator. Am going to get some binoculers and have a closer look, but cant see why it has started to show high SWR. Does any one else have this problem. I have discussed this with other guys and they dont normally have problems with ice and feeders in the winter. Only -2 here and not exactly artic conditions.. !!
All the best
Andy Cashel Co. Tipperary Ireland.. reply via email also..

Ice can detune your antenna if the wires are coated significantly.
True for Hex-Beams as well as any other wire antenna.

Hey again Ralph,
ok ik zal het deze keer in het nederlands doen hihi.
Wel als je niet te ver hier vandaan woont kan je van het weekend es komen kijken op onze contest-lokatie: nl. in Schaffen bij Diest.
Dit weekend doen we mee aan de ON SSB contest met de 5-band HEXBEAM. Mocht je de kans hebben eens te komen kijken; altijd welkom, wat je ziet hoeft dikwijls geen uitleg !!!
Bovendien is de konstructie vrij eenvoudig en vooral ,met huis-tuin-en- keukengereedschap te vervaardigen.
Dus.....
Indien interesse, vrijdag avond haal ik de beam hier van de mast en Zaterdag morgen monteren we het hele geval op de contest lokatie.
Je laat maar iets weten.
Met vriendelijke groet
Marc

Chas,

Traffie will do so, but not what you want I fear. He is making me a 40 m version now and I asked if it could also have 30 m. He has tried to do this in the past, but the 30 m part degraded the 40 m performance ... so no 30 m for now because I want top 40 m performance. He has also looked into making a 30-20-etc. HB, but that too had degradation problems. Yes, it works, but not up to the standards he has set and I, for one, agree with as what I want too. Nevertheless, give Mike a call.

1896. HexNut Partyline versus 17 meters

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-02-01 23:03:41 UTC
From: w6hb
Topic: 1896 Message: 1896

Hi Folks,

We had in individual break in / check in to today's Partyline who voiced a concern that we were violating the "rule" of "no nets" on the WARC bands. As a users' group, 17 was originally selected to minimize interference to and from contests and operating events. The thought was that it would provide the best compromise frequency-wise for the most folks given the current point in the solar cycle. As a users' group it was thought that it would be no different than a ragchew with many participants and open to anyone. Last week we QSYed for a QRP net on 18157.5. The meeting frequency was chosen subject to QSYing if occupied. The recommendations of all are requested. What are you opinions and suggestions? Should we seek a non-WARC band or is this a non-issue?

73

Doug - W6HB

1897. HFpack 18157.5kHz and Hex Beam Net

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-02-01 23:39:44 UTC
From: KQ6XA
Topic: 1897 Message: 1897

There have been recent reports of QRM between the new Hex Beam net on 18156 kHz and the HFpack calling frequency 18157.5 kHz. HFpack operators often run battery power and portable antennas, so it is easy to miss them in the noise. But they are there talking to each other nonetheless.

May I respectfully suggest that we try to coordinate, and I can offere a few slightly different frequencies in the following list that might work out better, with less QRM, for the Hex Beam net:

18152.5 (Clearest)
18155.0 (Shared with Live-Wire group)
18162.5 (Clear)

Background on HFpack and 18157.5kHz:

Founded in 2000, HFpack, The HF Portable Group has about 4000 members worldwide, and is growing rapidly. 18157.5kHz became the calling frequency in February 2001. HFpack operators monitor and give priority to portable, mobile, and low power operators. Everyone is welcome to participate (portables, mobiles, or bases). As a result of the efforts of many HFpack operators around the world, 18157.5 has become the prime worldwide calling frequency for low power and portable SSB. Hundreds of operators can be heard on it regularly each day. In mid-2001 HFpack formally established an open net, listed 18157.5kHz USB in the directories, and a crew of HFpack Net operators converts 18157.5 to net operation at certain scheduled times (listed in ARRL net directory). In the event of emergency, the HFpack Net crew is mobilized by a special email network and by announcing the net on 18157.5 in voice and CW. In 2004, HFpack established an HF remote base network called "EchoPack" on 18157.5kHz USB using Echolink. If you have Echolink, you can just click on the stations and listen to the frequency from different locations around North America. Several of the "EchoPack" stations also enable HF remote base transmitting on 18157.5 through Echolink.

Hi Doug,

There is no rule about 17m being free of nets. In fact, there are several 17m nets listed in the ARRL Net Directory. Traditionally, nets tend to gravitate to other bands instead of 17m due to the propagation. 17m propagation can be good or very bad, depending upon a net's objective. When the band is open, there is normally a skip zone of about 750miles... so it is often difficult for regional QSOs. This increases the difficulty of maintaining some sense of order in a net. But for casual roundtables, like the Hex Net, 17m makes a great band.

Bonnie KQ6XA

1899. "Open" 17m Freqs

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-02-01 23:57:17 UTC
From: KQ6XA
Topic: 1899 Message: 1899

When starting up a net, it is always difficult to find just the right frequency spot in the band. Several years ago, when HFpack started up, we used spectrum analysis to determine the "holes" in the 17m band.

Here is a list of currently the most dependably clear 17m frequencies that are not activated by a regular group yet:

18142.5
18147.5
18152.5
18162.5

1900. Re: HexNut Partyline versus 17 meters

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-02-02 02:00:54 UTC
From: w4wb
Topic: 1896 Message: 1900

Hi Doug and All,

No, 17 m isn't required to be NET free. Bonnie has made a few good points, but I note that HFPack is highly informal and 18.1575 is a self-proclaimed calling frequency with no special privileges to have clear sailing 24/7. The FCC rule of frequency use applies.

That said, we can easily move our informal meetings, that occupies maybe a total of two hours a week at most, down 1 KHz to 18.155 or maybe up 18.160 or something else. Frankly, folks getting into our discussions have no real problem being heard if they are using a Hex-Beam! hi hi

If you have any thoughts on moving the frequency, pse send them to Doug and I will change the home page on the web site if the decision is to change it.

1901. Hex Beam frequency

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-02-02 05:37:09 UTC
From: Meiselman
Topic: 1901 Message: 1901

Hello to all:

Well, the mystery occurred again today. At about 10 minutes prior to the start of the net, I had a S8-S9 noise on 18.156. Then went away, only to return about 7-10 minutes into the net. I was not even to say 73, etc...just had to give up. Very narrow range...18.155 and 18.157 were OK.

I have no idea about the cause (have turned on and off all possible sources in the house). Will keep checking, but a slight shift might allow me to take part in the HB festivities.

[Of course, if you don't want "words of wisdom" from Altadena, CA....keep the 18.156...)

1902. HexNut Partyline

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-02-02 06:40:45 UTC
From: w6hb
Topic: 1890 Message: 1902

Hi Folks,

A search on the ARRL Web site finds several wide area "nets" registered on 17 meters. HFPack is found on 18157.5, OMISS uses 18165, the World Scout common is on 18140, and there are SSTV nets on 18160 and 18162.5. Given that we are really a users' group and function in a coordinated ragchew format primarily discussing technical subjects, I would think that few would begrudge our use of a frequency for 1 to 2 hours a day, 2 days a week. It is agreed upon that we do not claim or homestead a single frequency. We merely designate a frequency and select pluses and minuses to accomodate other users.

In an effort to accomodate and coordinate with other nets / roundtables / or whatever, we might want to QSY down to 18152.5. This might clear up some users' QRN /QRM problems as well. If a majority would like to move down to 20 meters and compete with the density and contesting, we can do that also. Please provide your feedback not later than Wednesday, February 4th, so all can be made aware of the decision.

73 - Doug - W6HB

From: Barry Baker
Topic: 1890 Message: 1903

In the interest of all concerned, I think 18.152.5 sounds fine. If it doesn't work, we'll try something different. I am sure we were crowding the HF Pack guys. Additionally, the move may solve Herb's Heterodyne issue.

On the 20m issue, I am located in the Mid-West, and the 20m band would make Texas and Georgia easier for me to work. I am only one single voice, and will be plenty happy to keep playing on 17m.

A search on the ARRL Web site finds several wide area "nets" registered on 17 meters. HFPack is found on 18157.5, OMISS uses 18165, the World Scout common is on 18140, and there are SSTV nets on 18160 and 18162.5. Given that we are really a users' group and function in a coordinated ragchew format primarily discussing technical subjects, I would think that few would begrudge our use of a frequency for 1 to 2 hours a day, 2 days a week. It is agreed upon that we do not claim or homestead a single frequency. We merely designate a frequency and select pluses and minuses to accomodate other users.

In an effort to accomodate and coordinate with other nets / roundtables / or whatever, we might want to QSY down to 18152.5. This might clear up some users' QRN /QRM problems as well. If a majority would like to move down to 20 meters and compete with the density and contesting, we can do that also. Please provide your feedback not later than Wednesday, February 4th, so all can be made aware of the decision.

1904. 17 Meter "Party Line"

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-02-02 13:28:51 UTC
From: schlott_98
Topic: 1904 Message: 1904

Hi Doug,

Enjoyed the group yesterday. I heard everyone yesterday except for Georgia which is unusual for me as I usually have a pipeline there. My personal feelings about the frequency are that life is short and I don't see a problem with moving to a different frequency on 17 meters. I found no noise at this end yesterday but on the Saturday group I did experience a very narrow "roaring" noise and in addition I heard a hetrodyne that persisted for hours. I could get rid of it though using the auto notch on the pro.

I might suggest that we do have an alternate frequency to use on 20 meters in the event that the propagation on 17 is poor. This would be a last minute change though and might require someone to monitor 17 meters and direct people to the new frequency on 20?? I have my 706 home for the Winter and could monitor and send folks to the 20 meter frequency.

From: lengail2
Topic: 1906 Message: 1906

Does anyone know about maximum wind load on a Radio Shack 40' mast under the following conditions:

The base of the mast will rest on a deck 10' above ground, and it will extend 17' to the edge of my roof and attached at that point.

That will place the hexbeam about 27' above the ground and only two mast sections above the deck.

Will the mast support the hexbeam and small rotor without guy wires? The mast will only extend about 3' above the roof.

Another concern is that the eve of the roof extends 2' from the side of the house, not allowing the mast to be placed against the house. Do metal fixtures exist for holding the mast about 2' from the house?

The company owned Radio Shacks only sell an 18' mast in this area because of local laws, but independent sore owners do have the taller versions.

From: htankin@comcast.net
Topic: 1906 Message: 1908

My HX5Bi is mounted on the Traffie 30 foot HDX mast. The rotator is mounted 2 feet above ground on conduit. The rotator, therefore, turns the mast and antenna. The mast is guyed at 2 levels, 3 points each. It's been up for nearly 3 years and works great.

I would advise against your proposed arrangement unless the mast is (a) mounted (not sitting on) on the deck, and (b) attached to the house (or guys are used). Further, you may find the combination of antenna and rotator at the top of the mast makes erecting and MAINTAINING the antenna unwieldy and difficult. You should drop the top sections of the mast periodically to check the antenna and "service" it (I do this twice a year with my HX5Bi.) That may be cumbersome with the rotator on top (especially if anything other than a TV-type rotator).

1909. HexNut Partyline Users Group Roundtables move to 18152.5 MHz

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-02-04 06:00:30 UTC
From: w6hb
Topic: 1909 Message: 1909

Hi Folks,

Effective February 7th, the HexNut Partylines will QSY to 18152.5 MHz (+ / -). This move has been coordinated with the HFPack group who uses 18157.5 MHz and should give both groups adequate breathing room. Naturally if 18152.5 MHz is in use we will locate another clear frequency. After reviewing the ARRL's 17 meter net postings and assessing prudent usage of 17 meters, the concensus reached is that our operations utilize no more spectrum than any single QSO. As such, since we do not work split those consulted see no logical reason why we should not continue to regularly meet on 17 meters. We may occasionally QSY to other bands in pursuit of the illusive HXCC award. Suggested other frequencies commons are 14256, 21356, 24956 and 28356 MHz. As always the opinions and suggestions of others are entertained.

Am considering the purchase of this antenna, it is the 5 bander, I believe. I have just the reverse situation as you. Already have a very good performing heavy duty Cushcraft X7 tribander, but must sell as am moving to new home where just do not have the real estate now have, and touchy neighbors to boot. Can only have an antenna that does not project more than five feet above my roof peak. Guess this to be about 35 feet, and am considering this antenna or perhaps the steppir 4 element yagi. Is your tuned to your custom specifications upon purchase, and if so, what were they for each band? Or, did you just purchase the default setup as Traffie sells it? I do mostly phone and have little interest in CW, and am under the impression, correct or not, that if I purchase new, can order each band with the phone band tuned to the center freq I might choose. Any comment on any of this and your evauation of this antenna would be appreciated. Thanks, Bill/k3yc.

HexNut Partyline

All amateurs with an interest in the Hexbeam style of antennas are
welcomed.
This group meets twice weekly on 18.1525 MHz (+/- QRM)
The Asia-Pacific session meets Saturdays at 2300 UTC.
The USA-Europe session meets Sundays at 2000 UTC.
This is a moderated session.

Perhaps you were on the wrong day. The USA-Europe session is on
Sundays. Hope to get on today myself.

From: Johnny
Topic: 1915 Message: 1915

Howdy to all,

I was just wondering how a hex-bead would work if you mounted it upside- down. Like an umbrella. A friend has a height limit. He only has about 18" above where he can mount a rotor. Including the rotor height. But if the hex will work as well upside-down he will have enough clearence to mount it and rotate it.

Will be greatful for any and all input. And would like to say thanks in advance.
Johnny

Nike,

The HX-5Bi comprises 5 wire beams stacked using the same support
arms. A single feed line is used, so you can change from one band to
another as fast as your radio will do it. Makes band hopping just
simply easy as can be!

No. True multi band antenna. The HX5Bi should NOT be confused with the HexPac which is a portable Hexbeam antenna with optional bandpacs (elements). It is a monobander, and to change bands you replace the bandpac for operating band you want.

1921. WPX TTY - hexbeam experience

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-02-17 11:01:26 UTC
From: iz5diy
Topic: 1921 Message: 1921

Hi guys,

last week-end I run the WPX TTY Contest.
I use my homebrew 3 band Hex antenna (for 10 - 15 -20).
It was my first time with an hard duty with hexbeam and I had good feeling. Other part of my station are IC775, 200W and a windom antenna.
I can compare signal with windom antenna and specially for qso from far zone I note a really better signal on hexbeam.
Antenna was at 9 mt of height and it is still a beta version (I am planning a tower and a fixed installation).

73, Silvio IZ5DIY

1922. new multiband version eznec files

Yahoo group: hex-beam (2001 — 2006)

From: dl7io
Topic: 1922 Message: 1922

Hello,
while laying in the hospital with serious broken bones and cutted tendons after skiing I used the time on the notebook simulating new multiband versions. As we already have a good working design for the highbands my focus was on a lowband antenna starting from 40m to see how many bands are possible to get together with a usable gain and swr. For those of you who have eznec3.0 I can offer models for versions 30/40m, 20/30/40m, 17/20/30/40m (my favorite) and 12/17/20/30/40m. See in the file section under DL7IO. I also had an idea for a new and totally different base unit which is a fold together unit and better suiting for DX-pedition-like operations as what we use today (no U-bolts needed etc.). Will go to the mechanical garage in my village and ask the guy to build me a prototype. I already ordered spreaders for the 40m+ version.
The problem is that I only have my right hand/arm for working because my left side (shoulder) is still unavailable but full of titan screws and wires.
regards Holger
PS. any feedback regarding the models is most welcome

Hi Holger,

You are a true enthusiast of Hex-Beam if you continue your work even in the hospital! I wish you a quick an painless recovery.

I would like to try your models, but, since I am a casual user of antenna modeling software, I use the freeware 4nec2 program instead of EzNEC. Is there a tool for converting between the EzNEC and 4nec2 file formats?

It would be great if you could post some figures illustrating the effect of the 40 m elements on the antenna performance on other bands. Since you already ordered the spreaders, the figures must be encouraging ;-)

I am wondering if EzNEC can model elements made of coax. According to N0KHQ (http://www.hamuniverse.com/17mcoaxmox.html), an antenna with coax elements is up to 40% smaller in size, while its performance is almost the same as that of a full size antenna. This could make a 40 m HexBeam much more affordable!

73 Alex VE3NEA

Hi Holger,
Hope your bones etc, will recover soon and you are able
again to work with your new HEX-beam design. This weekend I removed
all my dipoles, VHF/UHF and 11M-antennas, to make place for the HEX-
beam.
Hope this weekend the weather will be good and the HEX-beam will go
where it belongs....on the mast at my dormerwindow (that's where my
shack is located). I decided not to place it on my chimney, because
at this place I have much better access to align and repair it.

Best 73's and hope to work you all soon with my HEX-beam.
Jan de PA2JJB

PS hope we can make a earlyer HEX-beam net so all the guys from
Europe can also parcitiate in the net !!!!

Hello to all,

I was looking for a not too big and conspicuous antenna and was thinking about constructing a vertical Delta-Loop with nested wires for 10m - 20m. Deltaloops are less sensitive for QRN and usually have flat elevation angles. However my antenna simulation with the free MMAna software showed odd results.

While I was looking for some hints on the internet, I stumbled over the hex-beam. Due to its small size, it might be a good choice for me. Since it is a two element directing antenna it even provides some gain.

Now my question: Does anybody know the elevation angles of the HX-5Bi 5-band hex-beam from Traffie? Since Traffie does not mention them, I suppose that the angles must be modest compared to other antenna types?

Hi George, there are some elevation angles in the files section of the group site. I don't remember exactly where but I downloaded several about a month ago.

I have been using a Hex Beam for about a month now and I am very pleased with its operation. I have the HX-5B and is mounted only 7 ft off the ground. I can't go any higher due to CC&R's but it seems to work good for me.

George:

Here's an email from the reflector that I saved from last summer. I haven't checked to see if the file is still available on the Web site, but if they aren't, you can probably get them directly from Dave, VK2DPD.

Subject: Elevation Angles - Optimum Height

Hi All,

I've just uploaded a Excel File to the files section which shows elevation angle information for the 5 Band Hex-Beam at different heights (between 5 and 20M), and for all 5 bands.

There is a section in the ARRL Antenna handbook that details the optimum radiation angle from various areas in the US, to the rest of the World. Therefore in theory you can set your tower height to the optimum for a particular part of the World you prefer to work.

Sounds easy Eh?? Well if you prefer to work one location, on one band, only using 1 path (long or short) it is. However, if you want optimum height, for all bands, on all paths, to all locations you want to invest in an automatic telescopic tower!

1932. Vertical Hexbeam?

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-02-25 15:18:18 UTC
From: Colin
Topic: 1932 Message: 1932

A 40m Hexbeam is a nice pipedream for most people,due to the sheer size and ideal mounting height constraints.
It occurred to me that a 40m vertical Hexbeam could be much easier to build and fit into a limited space and should perform quite well mounted low to the ground.

If you have enough space it would be fairly easy to erect a 50ft tall wooden,fibreglass,pvc? mast and use 2 sets of 4 non metallic guyes to support the mast and the element wires (no spreader arms required).

I doubt many have sufficient space for the guyes` 30 degree slope from 50ft but it may be a possibility for a field day or special event.

A couple of crossbooms may be a realistic alternative for the home qth and reduces the real estate needed for guyes.
Like a diamond quad loop the crossboom would receive support from the vertical spreader (or mast in this case).

The Hexbeam has a fairly wide azimuth beamwidth when used horizontally so i guess it would be VERY wide as a vertical antenna (which is good because you wouldn`t have to(or want to)rotate it too often.
The elevation beamwidth of vertical arrays is usually very uniform covering a lot of angles with equal strength.

The Hexbeam is a real performer when used on the flatside..maybe it has equally surprising performance when used as a vertical on the lower hf bands.

Best Regards
Colin

That's good to hear. I can't install any antenna on a support higher than 7 ft
above the roof top for the same reason.

Apart from that, storms with up to 100 Mph can occure here, and I want to
sleep well...

We just went through a couple of days of extremely high winds -- gusts near 75 mph. A whole row of power poles went down plunging us into darkness (we live in the country, so no power also means no heat and no water). My Hex-Beam HX-5bi on top of an HDX-30 mast came through with flying colors (I'll keep my fingers crossed, touch wood, etc. for the next big blow!). Thank goodness for the strudy quality of the antenna and mast and the low wind profile of the HX-5bi.

Folks,

What is the shipping size and weight for the HX-5Bi?

I would love to use one here in Iraq but the size and weight limitations for APO mail seem to be "Parcel Post(r) not exceeding 30 lbs. in weight or 60 inches in length and girth combined" which may preclude shipping one over here. If the shipping size is too big and/or heavy would it help to break up the antenna into multiple boxes?

Thanks and 73,

Charles

1937. HX-5B on 30 m

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-02-28 22:54:20 UTC
From: w4wb
Topic: 1937 Message: 1937

I was playing around yesterday and worked an EA8 on 30 m who had a big pile up going. The HX-5B clearly was showing 2 to 2-1/2 S-units F/B and the F/S was a bit more. Who knows what the gain might be, but I did get through the pile.

Was using a FT-1000MP and VL-1000 (in stdby mode) followed by a AT-1000 autotuner. The AT-1000 makes short work of tuning the HX-5B on 30, 40, and 80 m. Normally, the AT-1000 isn't in the circuit.

From: Meiselman
Topic: 1938 Message: 1938

Dear All:

I am prompted to send this email by the very recent one from Barry (W4WB).

Since I love my HX-5B (and it loves me...most of the time), I wonder what damage, if any, could occur with operation on 40 or 80 or even 160? I would not run an amp and so probably only 80-90 watts from my 756ProII.

I have a 40-80 dipole but it is really not too useful. The HX-5B is much, much better on 160 for receiving, but its SWR is about 5+ (tested with low power). Since 40, 80 and sometimes 160 are active during my waking hours, would be fun to use the HX-5B rather than the dipole.

Thanks for any and all comments.

Hi Herb,

Nice to "hear" you agn. Not much is really known about damage, but I am totally confident that you will not hurt your beloved HB by using it on the lower bands. You will need a good tuner. Don't worry if the SWR is high since the feed line loss is very low at the lower frequencies. Mine didn't tune on 160 m in the past with the AT-11MP tuner, but I haven't tried it with the AT-1000. Might just do that sometime.

FWIW, when I ask Mike abt pwr limits on 40 m, he suggested it not exceed 200 W for no good reason other than that was his thought. I agree, but just run 100 W on these other bands.

Let us know how you make out and try to make a comparision to your dipoles.

From: Ken Hopper
Topic: 1940 Message: 1940

Dear HexBeam-ers,
I am the proud new owner of HX-5Bi #287
that was formerly owned by Bill K3WA.
It is in perfect condx and went together
just fine. Picture here:
http://www.n9vv.com/Images/HexBeam-2-28-2004.jpg

I want to put it on the roof of my garage and
don't know how. I know about rotor mounting plates
inside towers, but is there any sort of rotor
mounting plate for a rooftop installation? I
don't even want a mast - just roof + rotor + beam
to keep the profile very low for now. I will figure
out a tower/mast in the future.

Anyone know of a commercial roof top rotor mounting
solution?

Ken,

The idea is to shunt the RF on the outside of the coax shield. I have not used these, but the use of the Type 77 ferrite beads from Amidon has been shown time and again to do the job. You need 5-6 of them at $2 each. (Use 8 is you like too.) Hold in place with heat shrink and tie wraps. Overall length is maybe 6". Be sure to located just below the base of the Hex-Beam.

Another choice is the DX Enginerring balun, but it costs 3 times as much (or lots more depending upon version) than the beads.

From: Johnny
Topic: 1944 Message: 1944

Hey Colin,

I'm new to this area, but it seems to me that going vertical would be defeating the idea behind the beam, hex or not. I may be out in left field, but the reason the hex-beam works so well in that the signal is reflected in a horizontal plane. If it was vertical would'nt the signal be sent straight up or down, depanding on the orentation of the reflector? Seems like it might be good for moon bouncing, but that seems like all.

I might be wrong, but that is what the things I'm learning are telling me. If any one out there has more info, please let me know.

Thanks.
Johnny

Ken:

I use a coax choke -- about 8 feet of coax in a coil of 6-7 turns. The ARRL Antenna book suggests that this choke should be effective 14 - 30 MHz. I used wire ties to form the coil and have it taped to one of crossarms right at the base plate. It seems to work pretty well, and all you need is some "slack" in your feed line.

Hi Chuck,

In the files section of this group, you can find an excellent technical note by K1TTT. He made some very good experimental measurements to provide guidance. See the folder Publications and the file airbalun.html.

My experience with the coax balun vs. the ferrite beads (#77) is that the beads do a much better job. Yes, the cost is maybe $10-12 for the beadss compared to the $5-6 for the extra coax, but that seems incidental after you have spent a lot for the antenna and coax. :-)

The Wire Man sells a kit which is similar to the W2DU ferrite balun. The kit consists of a large quanity of ferrite beads that are placed over a length of low loss coax also provided in the kit. You provide the type of enclosure you want. I used a 12" length of 1.25" PCV pipe with end caps.

Hi All,

Check out the 2 photos of my "stealth" Hexbeam installation completed Jan 3 2004. The spreaders are invisible against the trees by using Krylon camoflauge paint !!! I wrapped the mast in camoflauge duct tape from Wal-Mart. (Copper wires turn brown and become invisible by themselves - - do not paint according to Mike Traffie). Tower is a Force 12 LPT 1242 w/ optional green power coat cranked to about 36 feet, with custom stub-mast for Radio Shack TV rotator. Note this set-up replaces the ladder - mast I wrote about back in October 2002.

73,

Art NF1A

From: DrRodney
Topic: 1952 Message: 1952

Hello All,
I'm NA9N and am in southern Wisconsin. I'm curious about the use of the Hex-Pac on portable operations/dxpeditions.
To celebrate our 15th anniversary, my xyl has agreed to our visiting Rarotonga in the South Cook Islands during the last week of December. Cook Islands Telecom has reserved the callsign ZK1ROD for me. I've been searching for a good portable antenna to take with me and am looking at the Hex-Pac. This is a dream come true, as I've never operated as DX before.
Here at my home QTH, I currently use only a vertical and a G5RV. I'd like to use something with a bit more directivity here but which will allow me to easily take it down for portable operating around the state and for use on Rarotonga.
I was wondering if anyone could tell me how the Hex-Pac has worked out for portable operations/dxpeditions. I'm especially interested in how folks have been able to get it on planes as checked baggage. The dimensions, with the mast, seem to be greater than the baggage limits on a number of airlines.
I thank you in advance for any thoughts or advice you might have about the use of a Hex-Pac.

With my best 73,

Rod Marty, NA9N

1955. how to mount to mast?

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-03-17 16:58:42 UTC
From: Ken Hopper
Topic: 1955 Message: 1955

Dear Hex-beamers,
I need some help to understand how to mount
a HX5Bi to a mast. Is an adapter required?
if so, which ones are available? I have one
that came with the HX30 mast, but I have
decided to use a 5ft single mast section on
a roof top tower instead. Which size (ID/OD?)
mast section should I purchase? any suggestions
for a supplier?
Thanks,
de ken n9vv

Hello to all HEX fun?s

Well... I?m new in this group and possible I?ve missed
?something? :-) ☐ so have a question:
Did ever anyone tried to feed multiband HEX with
separate feed lines (coaxes), e.g. completely
separated or via remote ant. cable switch and what
result has been achieved, how big was a difference
between initial/original setup and after modification.

73 to all !

Hi Ed,

Actually, our friend in the "Down Under" (VK-land) tried it and found
that it worked better as I recall with the common feed.

Hope you are doing well. Haven't heard you on yet.

73,
Barry W4WB

1959. HX-5Bi about to go up

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-03-19 20:25:51 UTC
From: Sean
Topic: 1959 Message: 1959

Hello All...

After being a radio hobbiest (SWL and Amateur) for almost 30 years, I am finally in my dream QTH with room for a tower and proper antenna array! I've purchased a HX-5Bi from Mike and will be mounting it on a Trylon T200-40 with a Yaesu G800SA rotor. The apex of an 80m dipole will be mounted at the 35' mark. This is the first (and hopefully only) tower I've ever put up.

I think I've thought of everything (Polyphasers, grounding block, good quality coax, coax seal, thrust bearing, etc etc,including the Amidon beads)and plan to start construction as soon as the snow melts and the ground is soft enough to start digging.

Any words from the wise on making this all work???? I know it's a wide open question, however I'd really appreciate any tips as I only have one shot at doing this right.

Many thanks!
73
Sean VE3OZ

1960. 6 meter hexbeam

Yahoo group: hex-beam (2001 — 2006)

From: t_ashland
Topic: 1960 Message: 1960

Hi,
I'm interested in building a 6 meter hex. I would like to hear from anyone who has built one. I would like to know the specs (dimensions, materials, etc.) I see K0TRL had a frozen photo of one in the photo gallery, but I can't find his e-mail address. I have a commercial hxb5i and love it. It loads up on 6 meters, but I think a 6 meter hexbeam cut for the band would be much better.
Thanks and 73,
Terry, WK0F

This is the first time I have ever tried posting a message in any group and I couldn't find the place where you ask what may be a new questionbut anyway I am going to build a hex beam primarily for 20 meters but other bands as well after I get 20 working. I have some measurements the the elements but they talk about tip spacing for driven and reflective elements. They dont say what the distance for the tips are in reference to. Can some one tell me this or does someone have a little better descriptions of measurements for the hex antenna.
thanks

http://www.qsl.net/aa5tb/loop.html
http://www.kr1st.com/magloop.htm
http://www.eham.net/articles/7712
http://www.iri.tudelft.nl/~geurink/magnloop.htm
http://www.btinternet.com/~g4fgq.regp/page3.html

in a nutshell, they seem to work very well for restricted space operations. They do require a high-voltage capacitor (preferably vacuum) but there have been some interesting designs for alternative capacitors one can homebrew (i.e. sliding plate and trombone).

my interest is mostly in lower noise 80 and 40 m operation in contrast to a dipole. Can't seem to find any leads telling me how it performs in relation to a dipole or inverted L because it seems that if you have the space for one, you have no interest in the other. I also must admit that copper tubing for an 80 m loop is a bit expensive if you're just going to "try something out". It would be interesting to see if copper screen over PVC would work as well as copper tubing. I also haven't had any questions answered on whether or not copper oxidizing reduces effectiveness of antenna.

I may try a 14 MHz to 29 MHz version as an experiment to see how it deals with local noise, tuning, and if rotating makes any sense given its radiation pattern. Then I'll move down to the 80 m version.

Hello Kevin or Adam?
you may go to the file section under dl7io or to my webpage
(www.dl7io.de). There you will find EZNEC files for a handful of
versions that include 30/40m and if you use the "view antenna"
funtion in eznec you can determine how the feeding is done is this
models (low impedance line, feeding from the bottom!).
I will get the last parts (my new base platform) at the end of next
week and will start directly to build/test all these versions. If you
will give me another month or 2 I sure can present you the results.
Or, what I would like most, try it out parallel for yourself. Than we
have two independent results.
regards Holger, DL7IO

Hello yo you all,
Today I've placed my HEX-beam on my roof; and its
lots of fun hearing and working all the DX. Worked 3B9C on 12M and
P43JB on 17M in my favourite mode CW. Its fun to turn the antenna
round the globe and hearing the stations becoming weaker and
stronger !!! The SWR on all bands look OK, except for 10M (>2:1); I
think is to short, because I used isolated wire I've kept the dipoles
and reflectors 10cm (about 4 inch) shorter, then DL7IO Holgers
dimensions. When weather is good I will try this weekend to measure
the HEX-beam with the AEA-antenna-analyser or the Rohde and Schwarz
spectrumanalyser, to see how the SWR-curve looks like.
Its was fun building this antenna, and thanks to you all who has
helped me to bring this wonderful project to a good end.

Special thanks to Holger DL7IO, Bud VE7ASK, Davy PE3AA and Lourens
PH1DX for all the usefull info they giving me.

Maybe we can make a HEX-beam-net for Europe on 17M or 20M, to
exchange our experiences with other radiohams. Hope to hear some
suggestions about that.

Best 73's de Jan PA2JJB

If I didn't screw up the URL below it'l let you access a site that will give
you
formulae for calculating various dimensions on hex antennas. Much of the
good
info is for down in the text. Fellow describes building a hexbeam, uses
wrong
numbers in his calculations, gets corrected figures and so on. Hes even got
a
little diagram with corner locater info. If you give it a thorough read I
think
you'll find what you seek. Remember, most of the good formula info is way
down
toward the end. Just read it thoroughly and don't be confused by his early
calculations.
(Which turned out to be wrong, neccesitating a do over for him.)

1972. First Measurements on HEX-beam and some quistions for alignment

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-03-26 21:22:48 UTC
From: PA2JJB
Topic: 1972 Message: 1972

Hello to you HEX-lovers,
This evening I did my first measurements
with the Rohde & Schwarz spectrum-analyser FSH3 on my HEX-beam (see
the 5 new pics in my photomap PA2JJB)on his final place on my roof.
The 15-12-10M are >2:1 so need some pruning; when I turn the beam SWR
changes; I think some old metal garbage on my flat roof is causing
that and will move it tomorrow to another place, to see if SWR
changes. Also I will change my T200 RF-choke by the 8 Amidon
ferritebeads sliding over the coax to see if this makes a different
SWR.

When I change the resonantfrequency of 20M dipole/reflector will the
SWR also change of the other bands or only changing the resonant-
frequency ????

Will chanching the distance between the ends of the dipoles and
reflectors also change the SWR or is this only important for the
front/back value ???

Thanks for your suggestions !!!

Have a nice weekend and many DX in the WPX-Contest with your HEX-Beams

Hello Jan,
while changing element lengths in a multiband version usually the two attached bands (+/-) are influenced. As bigger the distances of the wires are, as lower is the impact. That means for the 20m elements you will not see to much on the other bands. Have a look on 17m.
Changing the end insulators of the elements is for sure influencing the SWR and the gain. If the SWR is getting better you normaly lose some gain. But it is mostly in the second digit after the point while changing a cm or two. Will say every additional connector in the cable will cost you more gain.
Metal things nearby the antenna can have a big impact on the SWR. So try first to remove those things.
Have a nice weekend,
Holger DL7IO

Hello Bob,
Spent several hours and hours to align my HEX-Beam. 20-17-
15M are ok now and working fine I think, but 12 and 10M will not
going down the 2,6 point. Wonder if you had this problem, because
your HEX is also near your roof, Bob. What did you use for connection
between the dipoles on the hub??? Hope you can give me the answer, or
somebody else in the group.

Many thanks for eventually amswer(s) and maybe we can make a sked on
20 or 17m to talk about this beautiful antenna.

I have a tower that would be perfect for a hex-beam. I am selling my home and will not have a place for it other wise i would build a hex-beam and use it my self. the tower is about 32' tall.

the tower consists of a steel base that sits on the peak of the roof and suports a 18' mast that is guide in 4 directions. at the top is a hing that allows the mast to tip over. the mast is a alum. tube with 3/4 pipe in it that rotates. the rotator bolts to the base and conects to the rotating shaft. the rotator is a chanel master and is included with the tower. PICK UP ONLY I WILL NOT SHIP.
I had a 3 element 10 meter beam on it and it worked great. would be ideal for hex-beam. $100.00

1976. Another homebrew hex beam

From: Alex Shovkoplyas, VE3NEA
Topic: 1976 Message: 1976

Hello hex-brewers,

I have just finished building a 5-band hex beam. I used a lot of tips from this group, and the construction went very smoothly. TNX to all contributors, and special thanks to DL7IO and VE7ASK for the plots and a detailed manual.

The 10 ft. bamboo poles came from the nearest garden center. The poles and the plywood hub are protected with two layers of Krylon. Two weeks of rains followed by a snowfall proved that this is not a perfect protection, though. Something better should be found, or more layers of Krylon should be applied.

I made the feedline (the first version) of copper strap and placed it inside the center post. Most fixtures are also made of this great material - see the pictures in the Photos section.

With the feedpoint at the bottom and the antenna 1 m above the ground, the SWR was below 1.2 on 18/21/28 MHz, about 2.2 on 24 MHz, and well above 3 on 14 MHz (red sector on my MFJ-207). The SWR on the 'bad' bands improved a bit at 2.5 m above ground, but it was still not good enough.

I also had another problem, the 24 MHz driven element did not fit on the spreaders, and its resonant frequency was too low. Beleve it or not, it took me two days to put 2 and 2 together and to re-measure the 24 MHz wires. The reflector was ok, but the driven element was 2x20 cm longer than needed! I corrected the length, and the SWR went down to 1.2.

This trick did not work on 14 MHz, though. The 5 cm error was corrected, but the SWR stayed the same. I played a lot with the feeding scheme, trying different feedpoints and attaching short pieces of wire or coax between the connection points of the driven elements. Nothing worked. Finally I made another feedline of #8 wire and placed it outside the post, in parallel with the old one. The wire was too stiff to bend around the bolts, so I soldered the eyelets to it at the points of connection. Due to the eyelets, the spacing between the wires does not change near the bolts - see the picture.

With the new feedline and the coax connected to the 14 MHz element, the SWR is about right on all bands, though on 20 m it changes a little when the antenna is rotated, and increases significantly when the soil is wet. I hope it will still be low when I put the antenna on the roof...

1977. 40 meter hex-beam ?

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-04-10 16:04:02 UTC
From: va2rc_2000
Topic: 1977 Message: 1977

Hello, i plan to built a 40 meter hex-beam, but i'm new with this kind of antenna, can someone give me the formula to calcul the length of driven et reflector ? what is the distance from the bottom of the plate to the feed point ?

I have 20 feet fiberglass pole, is this lenght is enought for 40 meter hex-beam ?

Please help me

Thank you
Francois

Hello all,

Recently I've decided to "modify" my factory made 10-15m hexbeam
which served me perfectly in P5 - adding 12m band.
Well... I can say, I've succeeded, it was a lucky shot for me.
SWR on 10m is in a range of 1.3-1.8 (1.3 at the center frq. of
28.500), and both for 15 and 12m SWR is in range of 1.2 ☐ 1.4.
Front/back ☐ gave me steady difference on all 3 bands of 4-6 db
and at the around 130 deg. the signal disappears, as it is "predicted"
by manufacturer.
My roof is full of the metal garbage and nothing I can do with but I
put it up on HDX30 telescopic mast on a full length (10m) with small
TV rotor and think this did a good job, it's less affected by the
"unpleasant" surroundings.
Not using a choke at all, (may be have done mistake but neighbors are
happy :-) and me too!) was trying to avoid any additional parts and
with my only 100w don't have a problem to reach any spot in the
world if there is ConDX of course.

What I'm looking for:
I saw some other messages asking and wondering about the vertical
distance between elements for the multiband HEX.
Of course ☐ closer they are they will influence each other more
but what is the optimum? ☐ I would like to know too, does anyone have
an answer proved by experiments?

For instance, I've never seen myself the original 5 band hex
from MT but someone has of course - what is the vertical spacing there
and based on what(!!!), I mean calculations.

From: chris
Topic: 1980 Message: 1980

I've looked best I could at the messages archive but the terms are a bit generic, coax and elements appears quite often :)

In reading about the moxon antenna I ran across a version with coax used for the elements that boases a 30/40% reduction in size.

http://www.hamuniverse.com/17mcoaxmox.html

There is also a link from there to another page with some fairly technical analysis of it which puts it in its own category in his view.

http://www.hamuniverse.com/w4rnl.html

The remarks are from Cebik, who is much smarter than me it appears.

Anyway, what I was wondering from those here much smarter than me, does this method have a place in the hexbeam? Mostly its the weight of the coax that appears to be the problem, a 40M monoband hex with coax for elements might droop the other way. Although a mch shortened 20/15/10 might be possible with nice stiff spreaders.

anyway, just a thought. I have no modeling software etc, just alot of dreaming of something that will fit on the roof :)

-chris n0vrp

1985. Re: Max-Gain Fiberglass spreaders

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-05-05 23:09:12 UTC
From: wa2aae
Topic: 1651 Message: 1985

The lengths I used for the spreaders were a 8 ft length of 3/4" tubing and a 3 ft length of 1/2" rod. I allowed one foot of the rod to be inserted into the tube, giving a spreader length of 10'. I slit the end of the 3/4" tubing for about one inch to allow a hose clamp to lock the 1/2" rod in place. The fiberglass bent without any problems.

Harvey

Hello,
I wanted to let you know that my first try on 40m was successful.
The calculated dimensions for a 40m monobander fitted absolutely.
Radiator 1110 cm, reflector 1133cm, insulators 21/27cm.
The beam at 4m already outperformed my dipol at 8m. Now the beam is
at 17m height. The dipol (trap dipol 2 x 13m) has 2-4 S-units less
signal strength.
Will continue with multiband versions starting from 30/40m and keep
you informed.
regards Holger

Kevin!
Which version are you talking about?
The feeding for 40m is at a height of 155 cm.
For the 20-10m version please look in the file section under DL7IO
and download the pdf-file.

8 months old HXL-17 monobander. This is the real thing, genuine HexBeam from Traffie Technology. Outstanding performance in excellent condition. Complete with manual, box, just like from the manufacturer. Selling because of changing over to HX5Bi.
$225. E-mail direct to na1a@...

1991. New Products and Specials at Dayton - W4RT Electronics

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-05-08 15:58:46 UTC
From: w4wb
Topic: 1991 Message: 1991

Hi Folks,

W4RT Electronics will again be at the Dayton Hamvention in our same location, Booth #114 (across the aisle from Bob Heil's Booth). Hope you will drop by and see the new accessories and interesting specials we have this year. Some examples are as follows:

LDG Z-100 Ultra for $149 (this is the same as the regular price for the Z-100 alone!). This is a very special Dayton-ONLY price and applies ONLY to the stock we have at Dayton. No preorders and no backorders at this price. The Z-100 Ultra includes an internal battery pack (with batteries) and circuit mod that allows you to operate the Z-100 Ultra without needing to connect an external power source (but you still can). Nominally, over 10,000 full-tunes and many times more memory tunes before needing to change the long-life batteries. Really cool for portable operations.

500 Hz CW filter for $109 and the 2.3 kHz SSB filter for $125. This is a very special Dayton-ONLY price and applies ONLY to the stock we have at Dayton. No preorders and no backorders at this price. These excellent filters, built by W4RT Electronics, contain either a 7-pole (CW) or a 10-pole (SSB) Collins Mechanical Filter essentially identical in performance to that Yaesu uses in the YF-122C and YF-122S optional filters. Proper filter termination is an integral part of the W4RT filter assembly. Connectors like those on the YF-122C/S allow you to install and remove these filters just as you do with the Yaesu filters. Filter units contain the coding for the FT-857 or FT-897 to recognize it appropriately. Same filter fits the FT-817/ND too.

Wonder Wand Antenna for $99 (regular price is $134). This is a very special Dayton-ONLY price and applies ONLY to the stock we have at Dayton. No preorders and no backorders at this price. The Wonder Wand has been made as compact as possible, without compromising performance. Just pop it in a bag with your rig when going for a walk in the countryside or take it camping. Enjoy radio in the great outdoors without the hassle of erecting more complex antennas. Designed with the Yaesu FT-817, FT-897, and ICOM 703 in mind, the Wonder Wand can also be used on other low-power HF radios up to a maximum output power of 25 watts P.E.P.

Tuned Counterpoise System (TCS) for $89. The Wonder Wand TCS is a portable ground radial system designed to work with the Wonder-Wand antenna, although it will also work very well with other types of antennas such as the Miracle Whip or a long-wire/tuner combo. Quite simply it is a tuning box that interfaces the chassis of the radio to

a short 4m counterpoise, which is extended out over the ground. The best setting is determined by rotating the control knob until a definite increase in received signal is heard or best SWR is observed. Improvement of both received and transmitted signals is typical. Best of all, it is quite small and great for portable operation.

WonderPole for $149 (normal price is $169). This is a very special Dayton-ONLY price and applies ONLY to the stock we have at Dayton. No preorders and no backorders at this price. This is a brand new product that will be shown for the first time at the Hamvention. The WonderPole is a ultra compact dipole (about 12" total length when stored) having a deployed span of about nine feet. The design is related to the Wonder Wand and covers 70 cm through 20 m. This antenna is now a permanent part of my QRP "Go-Bag." It can be set up as a dipole or a vertical dipole and is easy to tune on HF by simply turning the band selector switch like is done on the Wonder Wand. It is rated to work with radios having up to a maximum output power of 25 watts P.E.P.

FT-817 Adjustable Stand for $29. This is a great stand that you just snap onto the FT-817 when you need it. Height is easily adjusted. This stand from bhi Ltd. has been very popular and we have a hard time keeping it in stock. We just got another shipment, but expect they will all be sold on Friday.

Hear It DSP Products. Drop by and try them out for yourself using one of our radios and actual recorded RF (using the ESS Time Machine having 80 kHz bandwidth). The performance of the DSP module in the FT-817 is hard to believe until you hear it for yourself. Check out our prices.

Antenna BOSS for $169. This is a very special Dayton-ONLY price and applies ONLY to the stock we have at Dayton. No preorders and no backorders at this price. The Antenna BOSS" makes essentially any motorized antenna "look like" the Yaesu ATAS-100/120 to the FT-100/D, FT-847, FT-857, and FT-897 radios. Now you can use your radio's own TUNE button for automatic tuning the way it was intended! The Antenna BOSS is simple to install and simple to use. High Sierra Antennas, Hi-Q-Antennas and Tarheel Antennas all work well with The Antenna BOSS.

We look forward to seeing you there!

Hello Fellow Hexbeamers:

"Yankee Doodle" reporting. (aka N0YD)

I've just uploaded a photo of the Hexbeam recently installed by Capt. Phil Gonzales HK3SA on his Amazon Queen located on the Colombian Amazon. Phil is a friend of mine. Ive been telling him how much I liked the Hexbeam so he now has one up on his wonderful river boat named the "Amazon Queen."

The Amazon Queen photo is the third photo in the last row on page 3 of the photos on this users group.

Hope you all enjoy this one-of-a-kind installation.

Tnx and 73,

Tom, N0YD "Yankee Doodle"

1996. 30/40m beam running

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-05-09 14:20:50 UTC
From: dl7io
Topic: 1996 Message: 1996

Hello,
today I changed the elements and the feeding of the 40m version for a 30/40m beam and it works. Same dimensions as calculated with Eznec.
The next test (version 40/30/20m) will be done when I'm back from the hospital. The titanum will be taken out of my shoulder on tuesday.
Hopefully I can continue next weekend.
dimensions:
40m driven ele. 1110 cm, reflector 1130cm, insulators 10/9 cm
feeding point 160cm from the base plate
30m driven ele. 766 cm, reflector 787 cm, insulators 19/15 cm
feeding point 80 cm from the base plate
low impedance line between the elements
coax feeding at 30m radiator
regards Holger

1997. 30/40m beam running

After a few hours using that beam I can confirm that it works...
I have been running a nice pile up of ja's with a few HL, ZL, 4S7 calling in on 30m and continued on 40m with another run of asian stations. And my call is DL7IO which usually never produces a pile up. Best was a ja1 with 5w (559 on my side) and a zl1 with 10w who was 549 with me.

Hi,

I think you have mixed insulators, 19/15cm on 40m and 10/9cm on 30m?

Hello Juha,
no it is correct. 40m has the shorter insulators. I was playing a
long time with EZNEC to get both bands working well. So I finally
came to this design.

2000. 20/30/40m version working

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-05-18 14:17:26 UTC
From: dl7io
Topic: 2000 Message: 2000

Hello,
today I build the 3 band version 20-40m.
Dimensions are like in the EZNEC file. I only changed the distance between 30m and 40m from 100cm to 80 cm. This was suitable to the element spacing in the antenna (conform to the shape of my spreaders) for 30/40m.
SWR on 40m is like expected (about 1:2 at 7MHz and going down to higher frequencies) and better than modelled on 30m/20m.

I only have done a few qso's on 20m and local QSO's on 40m. But signals on the beam are again much louder than from my trap dipole.
May be I can try to look for some DX in the late evening.

Here are the dimensions (element length means from feeding point/center hub to the spreader, which is only a half element):

band radiator reflector insulator rad./refl. side
40m 1052cm 1130cm 19/14 cm
30m 770cm 785cm 19/14 cm (yes, same dimensions!)
20m 558cm 566cm 16/11 cm

40/30m distance 80cm
30/20m distance 40cm

regards Holger

Bought a 17M monobander at Dayton. Put it up Monday evening last. SWR good. Performance so far? Par with my C3E/Tuner on 17. Hex at 28 feet, C3E at 46 feet. Par with my 40M loop/Tuner, loop at 55 feet in center. Mr. Traffie told me I'd get 6.0 dB gain with this antenna. I'd believe more like 2 maybe 3 tops. Also when I wanted a 20 dollar discount (Dayton Special?) Mr. Traffie he inferred I was cheap. (He actually said I was like him and other hams, cheap!) He was kind of a wise guy, I bought the antenna anyway.

I guess I'm glad I bought it. At least now I see for myself how it is made and can do a homebrew version for 30M. I couldn't see $500+ for the Traffie 30M version.

I had a great conversation with Mr. Traffie JR at Dayton. Very sharp young man. Dad needs to go to charm school.

You just need to wait until you have something valuable that you want to sell to the ham community. THEN you will understand and know what Mr. Traffie meant. Its obvious that you totally misunderstood his comment.

2004. Homebrew 20-17-12-6 Meter Hex-Beam

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-05-26 16:13:19 UTC
From: br_griffin
Topic: 2004 Message: 2004

Construction: 1/2" & 3/4" CPVC spreaders, #14 hard drawn copper elements, Ideal clamps & stainless feed thoughs to secure elements, UV treated dacron insulators & support cords, coax braid feed lines with RG-8 coax feed from the top.
Data Obtained using an Autek VA-1 Antenna Analyzer: Using DL7IO's dimensions as a starting point I learned that the insulator lengths on my beam were not critical w.r.t to spacing of reflector and driven elements to spreader. However, decreasing the distance between the ref. & dir. lowers the input impedence and increasing it raises the impenence. Since my intital impedence on 20, 17 & 12 were low (<50 ohms) I increased the insulator distances on 20 & 17. Little difference was observed on 12 meters. After obtaining the reasonable impedences on each band I decided to change the coax feed from RG-58 to RG-8U (foam) so I can run higher power. I also coiled the coax into a 12 turn choke below the antenna. This caused the input impedences changed dramatically. 20 meters went from 40 to 105 ohms, 17 M went from 55 to 75 ohms and 12 M went from 45 to 65 ohms. By changing the insulator spacing I brought the impedences close to where I started and have a SWR below 2.0 to 1.0 on all bands. I will tackle the 6 meter portion later.
Operation: Tests were done at about 25 ft. above ground with the antenna supported by a rope under a tall fir tree.
Conclusions: I need to do field strength tests to measure gain. Signal reports on 17 & 20 using 50 watts are good, but when receiving the front to back ratio is not as good as 3 el. 10 & 15 meter monoband beams I built. This is an interesting project and materials cost have been aroung $50.

The front-to-back ratio is going to change along with the impedance when you vary the spacing between the DE and reflector. The "best spacing" for front-to-back ratio results in impedances in the 25-30 ohm range.

I also found that my monoband hex experiments had a better F/B ratio than I could acheive with a multi-banded hex attempt. Tweaking one band on the antenna skewed the other. YMMV...

EZNEC does a good job at predicting optimum spacings if you are using bare wire....and the new version is supposed to handle insulated wire too. I found that the EZNEC model predictions for tip spacing matched what my ears could detect on the air and by my radio s-meter (using an attenuator pad receiving W1AW as a beacon).

The predicted wire lengths were not so accurate(from my EZNEC model to reality), but those dimensions appear to be very sensitive to maintaining the hex geometry very closely. I can see someone having problems because of this.

I found that small variations in geometry can slide the SWR resonance up and down. I didn't do a lot of listening, but the F/B ratio appeared relatively stable over a wide bandwidth if the element spacing between the tips remained constant. This is handy for monobanders, because you can then tune the antenna SWR resonance slightly by compressing or elongating the hex(maintaining the fixed tip spacing).

(Hmmm. That's a lot easier to "demonstrate" than it is to explain in writing.)

With a 2:1 transformer, you can get the nice flat swr and really killer f/b ratio. That's easier than tuning for a good 50 ohm match, with a multi band set up.

At least it was easier for me, since I had the toroid for the unun laying around idle.

Your mileage may vary....but its a great project for experimenting, isn't it?

2007. My first hexagonal beam

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-05-29 21:34:37 UTC
From: James Foley
Topic: 2007 Message: 2007

After reading through all the posts and talking to one or two on the air I finally decided to try building one. I have fiberglass spreaders and am using a circular aluminum plate for the hub. Everything is laid out in the back yard to get going. As soon as the light rain coming down stops I will finish assembly and see if my results match what I have seen published. The wire I will be using is #12 solid as that is what I have on hand (about 500 feet of it). Hopefully I will soon be checking into one of the nets using my own homebrew hexagonal beam. I am making it a duo-bander on 20 and 17.
Seeya on the air,

hi
this is the first time i have posted on this group.
i have just discovered the hexbeam about two days ago.and i,m keen
to build one..
i have searched through some files and instructions .but most are
basic regarding feeder attachment and wire length..and also spacing
for multi band hexbeams..with photo,s
i just wondered if any of you guys could point me in the right
direction

would really appreciate it

best wishes

Hello Andy.
20m
half driven element: 551 cm
half reflector elem: 569 cm
insulator reflector side: 11cm
insulator radiator side: 15cm

Monoband dimensions can be found in the excel file used for
calculating xyz coordinates. If it does not work here use my webpage
www.dl7io.de

...and for the one asking for in/ft dimensions:
1 inch = 2,54 cm
1 feet = 30,48 cm

or to be more detailed and complete:
1 inch (1") 25.399978 mm
1 inch (1") 2.5399978 cm
1 Foot (1´)=12 inches 30.479974 cm
1 Yard=3 feet=36 inches 91.439921 cm
1 Millimeter 0.03937 inch
1 Zentimeter 0.3937 inch
1 Meter 39.37 inch
1 Meter 3.280843 Feet
1 Meter 1.093614 Yard
1m=100cm=1000mm

regards Holger

Burton,
No, I have not done any field strength readings. I generally test things against my known dipole results on known beacon sources such as W1AW, using only my S-meter. I'm more interested in the generalities than the specifics. If it hears as well as the dipole did in the same orientation, I then hunt up a few QSO's to get reports.

Not too scientifically quantitative an analysis....but sufficient for my needs.

I experimented with the hex because I was looking for the F/B and F/side nulling more than I wanted any gain, and my homebrew hex did that quite well, considering how low I had it(only about 25 feet).

I have since cannibalized the hex wires and hardware for other projects. It was just a bit too large for 20 meters, and I have a nice rectangular loop for 20 that plays quite well for my needs, and I can pull that up to about 70 feet. I just can't get the hex high enough for it to really shine.

If I were able to put up a tower in the near future, I'd probably buy a hex for it, because I'd need the short turning radius, and I now know that they have good f/b ratios. For now, its wires in the trees, with the occasional experiment tossed in for giggles.

Sorry my replies take a while, I surf the news group archives only weekly on average.

I'd be curious to know what results you get when you perform testing on your installation. Does the near field match the model projections for radiation pattern? at what height?

good luck,
W4KAZ

According to eznec you only need 31 feet that is all the height you need.
And it do the optimal gain

2024. 20M Hexbeam

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-06-16 20:00:24 UTC
From: Darren G0TSM
Topic: 2024 Message: 2024

Hi all,
last weekend I constructed a 20M mono band hexbeam. I used Holger's dimensions with slight adjustment allowing for pvc insulated wire. I have some fibreglass spreaders but as this is my first attempt I used plastic conduit as I had a bundle lying around, I'll change to the grp spreaders later when (if) I get planning permission for a proper mast to put it on. The results are very interesting, the wire elements are only about 15ft from the ground but the recieved signals are exactly the same as on a 30ft high dipole. The big difference is though is that an S5 signal on the dipole is hard to copy due to local electrical QRM, switching over to the Hex the noise drops away leaving a perfectly clear signal. The front to back seems to be around 4-5 S units on either an MP or a 756pro2. The SWR is below 1.4:1 over the whole band but I do have 230ft of feeder on it, 50M of H100 plus 20M of RG213 (same lengths as on the dipole). When I've finished playing I'll add the other 4 bands and hope to get the finished version up to about 35ft.

It only took Sunday afternoon to build but I did get the hexagonal hub plate cut before hand.

Thanks to all for the advice and to Holger for the dimensions (from the file area).

Topic: 2024 Message: 2025

Hello Darren,
congrats to the project. Good to hear the antenna is working. The reduced noise level may have 2 reasons. Depending on the noise source it may be stronger if your antenna is at the same hight like your dipole. Nevertheless I guess the beam will be more quiet. I think the coupling between the elements is in the magnet field component (instead of the electric field like with yagis) because the elements are very close together at the ends and in the middle. That's why it sounds more like a closed loop and shows less noise like quads or magnetic loop antennas. This is very helpful in city locations where you have a lot of industrial and household noise sources. What forces me in this opinion as well is that the SWR is nearly not moving while changing the height of the antenna.
I wish you success with your next steps.
regards Holger

Regarding an earlier made comment that resonance and good SWR are not at the same frequency I will say that is of course correct. Resonance and a good SWR are two different things. At the point of resonance you usually have the best gain. How the feedpoint resistance is at this frequency is a totally different question. To get a good SWR at the same frequency you may have to match the antenna feedpoint to a resistance of your need. The towadays standard of 50 Ohms is given by the industry and the availability of TRVCR's, coax cables etc. The feedpoint resistance at the resonance point can be anywhere. Now we start to optimize the configuration with any kind of matching network (e.g. stubs, gamma matches, baluns or whatever) or with looking for small changes in the design. That is the case done here and means to find a compromise between easy direct feeding and maximum gain.

For this design or familiars like reflected M beams or X-beams you have at the resonance frequency a feedpoint resistance of about 25 Ohm. Changing the design to 50 Ohm means the resonance is at a lower frequency. So if you are gain focussed and talking about a single band solution you go for 25 Ohm design and feed this with a 1/4 Lambda stub of 37 Ohm cable (2 x 75 Ohm in parallel). Once you look for a multiband version it is much easier to use the 50 Ohm designs. Otherwise you need stubs per band or a balun.
If you have EZNEC or any other modelling software take a given design and have a look for 25 Ohm. This dip is much smaller but on the minimum SWR for 25 Ohm you will get more gain. By the way we are talking about 1/2-1dB difference. I have tried to design the beam so that we have a SWR of 1:2 at the CW portion of the band and best SWR is more in the SSB segment. SWR of 1:2 is a good compromise as you can use also automatic amplifiers without problems.

Here's another alternative approach to the same solution--just FYI.

For a single band, you can also use a more generic series matching section, with 25 ohm line made from 50 ohm coax you might already have on hand, if you already know or can measure its velocity factor.

Greg, W8WWV has a nifty series matching section calculator, and brief explaination at:
http://www.seed-solutions.com/gregordy/Software/SMC.htm

That calculator makes using matching sections a breeze, but matching to impedances lower than the cable impedances calls for paralleling the cables. The technique works well going up to higher impedances from 50 ohms using ladder line as the second line, or matching 50 ohm cable to 75 ohm scrounged CATV hardline(as long as its used for a single band).

For the 25 ohm hexbeam example, it works out to about the same amount of cable as the quarter wave solution, and its essentially the same solution.

For 14.15 kc, each section is 1.292 meters long, using 50 ohm 78% velocity factor Belden 9258 for a quick look-see. (Each section, both the 25 and 50 ohm, is .078 wavelengths * cable velocity factor)

O'course, for high power, you should probably use coax that can handle the load, rather than the relatively wimpy RG8x in my example.

Have fun,
W4KAZ

2027. SWR vs. resonance

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-06-19 14:03:19 UTC
From: vlatkolovric
Topic: 2027 Message: 2027

Hi,

thank You for comments, but I would like to stress few matters..

- I was thinking about MINIMUM of SWR (not the value)
- One should expect that minimum of SWR corresponds with resonance (more or less), where only real component of the impedance exists
- SWR (value) depends, of course of the antenna itself and impedance of the feeding cable and is a function of the frequency
- By my opinion, shift between minimum SWR and resonance of cca 250 KHz (on 20 m band) is a little bit too high

I was measuring right at the antenna´s feeding point and it could be a reason of the shift (increasing of the capacitance between antenna and surroundings (myself)) !

73, Vlatko

2028. beam height

Steve,

I believe for the HX5Bi 20-10m model..the optimum height is between 35 - 40 feet. Mine's at 30 feet and seems to have performed well over past 3 years. No complaints on this end.

Harry WE1X

ke4uyp has a nice explanation of ideal height (with eznec plots). He's talkling about dipoles and loops but the principle is the same.

http://members.tripod.com/~KE4UYP/index-loop-2.html

Basically, what happens is that as you increase the height of the antenna more than a half wavelength, the vertical lobe starts to split.

I have the bottom of my hexbeam at 32' so the 20 meter elements are at about 35-36 feet, about a half wavelength. I spend most of my time on 17 and it works great.

2033. Proper feedline arrangement

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-06-22 11:40:39 UTC
From: Paulo Marcondes
Topic: 2033 Message: 2033

Hi guys,

I didn't manage to understand enough of the feedline disposition...

A friend of mine is planning to homebrew one Hex-Beam for his scout group (I was once a scout, too), following some advice that I gave him concerning a better antenna for them...
When I was with them, we were always looking for a beam antenna... We looked at building quads, but that seemed too much complicated...
So I found the HB...
Well... I managed to explain him the overall layout of elements, dimensions, etc...
But what I failed to do is to explain him how to attach the coax to the elements...

I sent him the following drawing, trying to explain how to...

```
--------|-H-|-------- < this is Element 1
| H | < "H" is a common parallel wire,
| H | < like those used in house wiring...
--------|-H-|-------- < Attach it to the elements...
| H |
| H |
--------|-H-|--------
| H |
| H |<--------- This is the central post...
| H |
__|_H_|__ < The parallel wire goes through the base
H
[] < Here comes coax "[]"...
[]
[]
0- < PL259 to radio
```

Am I missing something? Or am I utterly wrong?

2034. Re: [hex-beam] Proper feedline arrangement

From: Darren G0TSM
Topic: 2033 Message: 2034

As I understand it, you connect the coax at the top of the common parallel wires. So in a 5 band hex you feed 20M first, 17M 2nd and 10M last.

At 11:40 22/06/2004, you wrote:

Topic: 2035 Message: 2035

ok , i have miunderstood the feed system apparently . do i
understand on a 5 band hex beam , that you tie all 5 bands to a
common feed for the driven & another one for the reflected wires
together to a single coax ground & feed to the rig ?
i was under the impression that you feed each band as a mono band
using a coax for each band (5 coax's) to a band swichting device to
a single coax to the band selector then to the rig .
apparently i am way off . am i way off ? please straighten me out .
i have looked at the diagrams & now i think i am confused ! lol
..... thx steve n6kkk

Normally the Hex is fed by 2 parallel lines down the center pole connecting all five band together and fed with the coax a couple of inches above the 20 Meter taps. It is explained in detail in the pictures and the Hex in 3 hours project. Also look at mine in the photo section N5GND. There are 2 parallel feed rods in the center pole that tie at the SO239 connector at the top.

Hi Steve
I think you get the best view on this page by DL7IO:
http://www.dl7io.de/reflectedw/files/reflectedW-design-en.pdf
Go to page 9, I think and you will see details.
You can feed all dipols with one coax, maybe separate is also an
alternative but not necessary. Just like any dipole,
feed to one leg and shield to the other leg of the driven element.
Reflector elements are stand alone, not connected to the feeder.

2040. feed #2

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-06-24 18:20:40 UTC
From: steve
Topic: 2040 Message: 2040

ok . good info . thx . good pix also . as i understand it : coax feed at the top , run 2 feed lines (as in a dipole) center feed from coax to one side on driven elements for all 5 bands ... ground feed from coax (braided) to the other side of driven element of all 5 bands . insulated from each other of course . reflectors are on there own , insulated from each other & driven elements . run coax to rig ..... thank you for all your help & patience . if i am wrong again , please let me know . i realize this is simple , but my brain sometimes does not engage correctly , thus big mistakes ! lol thx steve n6kkk

But fiberglass tube and rod from max gain systems is cheap about 80 dollars total with shipping.
Those fishing rods aren't cheap one rod cost as much as the whole 6 you would need to make a hex beam for max gain systems.
He will ship them via ups makes it so they telescope out to you length you need for even 40 meter thru 10m.

2045. Tube and Rod Sizes, was RE: [hex-beam] Fiberglass pole/rod source

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-06-25 23:17:37 UTC
From: Dave Simmons
Topic: 2041 Message: 2045

I agree that MaxGain is a good source for rod/tubes, but if anyone figures out a good combination of the sizes for the hex beam, please post them.

I purchased 4' tubes and rods (8' pieces cut in half to fit under the UPS shipping extra cost) with 1/4" rod, which fit into 1/2" and then 3/4" tube. The sizes all fit and telescope nicely for a 20-10m hex beam.

However, when bending the assembly, almost all the bend comes from the end 1/4" rod while the 1/2" and larger is much, much stiffer. I haven't spent time on this project since getting the tubing, but it seems like some other combination of sizes would work better.

Any ideas ?

- Dave

2046. Hex Beam Tubing and Wire dimensions, etc.

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-06-26 05:17:15 UTC
From: gfarek
Topic: 2046 Message: 2046

These are the Tubing dimensions I used that work out. They are from Max-Gain Systems, but only buy the 8 foot lengths, UPS will be considerable more, but the length and sizes work.
Qty. Size Length
6 3/4" 8 feet Tubing
3 1" 8 feet Tubing
1 1 1/4" 8 feet Tubing
1 1/2" 8 feet Tubing
Cut the 1 1/4" Tubing to make 6 pieces to go on your Hex base plate wirh U-Bolts and add the other sizes accordingly. By the way I used 1 1/4" U-Bolts and had to stretch them a little over a piece of barstock to fit over the Fiberglass Tubing. Only use the 1/2" tubing cut in 6 pieces if you need a little more curve at the end, it isn't necessary, some people like it better.
Wire I used was 14 Gauge Flex Weave 167 strand from Rf Davis, a little pricey but excellent wire for the project.
Band Driven Length Reflector Length End Spacings
20M 219" 222" 5" & 7"
17M 169" 172" 3.5" & 5.5"
15M 145" 148" 3.25" & 4.75"
12M 122" 124" 2.5" & 4.25"
10M 109" 111" 2.25" & 3.5"
These are usually within a couple of inches in being tuned correctly.

Mast Spacing (Approx.) From SO239
20M 1.25" 17M 17.625" 15M 22.625" 12M 27.88" 10M 30.25"
The bottom of the center section is wherever the 10M lines look straight. Go up from the with each to find all band straight rather than the mast spacing dimensions, they are close but may vary a little. Even if they are not straight the antenna still should work OK most of the time. Note the wire dimensions are for one leg side only, so you will need two of each of these cut. The Aluminum Hex plate I made was 12" and 5/16" thick, but 1/4" and 9.5" across the flats is good also. By the way you tip spacing at the top will be around 113" for 20 Meters wire. Now maybe this will give a few builders better insight. If anyone would like it I can tell you how to do the center pole and Feed connections too. Jerry Farek N5GND check out my photo section (N5GND)

2047. Thank you all

Thanks for all the source replies! Now one other question. IM sort of a neat freque and until I solve (cleanly) most of the percieved issues I dont generally start a project. Besides it lets me skate from doing work that much longer! Anyway, how do you attach the wire elements to the spreaders neatly and without using plastic parts (such as tie wraps) that are subject to UV failures? Is there some piece of hardware that will work on a tapered rod? Or perhaps a non tapered rod such as the MaxGain stuff previously mentioned. Or do most just thru drill and use a soldered wire around the thru wire to insure it wont break?
TIA
Chas

2048. 40/30/20/17m version running

From: dl7io
Topic: 2048 Message: 2048

Hello,
I have added 17m to the beam and it is working fine. I can also work on 15/12/10m without using a tuner. SWR is below 1:2. But I don't know how the antenna works here. I have to check it by EZNEC if there is any gain and/or directivity.
regards Holger

From: charlie11364
Topic: 2052 Message: 2052

Hi,
1st post here. I was looking through the various plans in the files section, but NONE are really clear on one figure - If you are building the 5 band unit, how long are the arms? DL7IO's plans don't really say. Bud's Bamboo Hex plans are not clear is the 9 foot 3" dimention is the lenght of the arm, OR the length from the middle of the center post to the arm when bent.

Anyway, I have most, if not all the materials lined up (I split one piece of bamboo, but I will splice around it, and I need to dig up "something" for the center), and then I'm ready to go

ISn't the 3 hours for putting together a commercially made hexbeam? It took me quite a bit less than 3 hours to do so. I had the help of a neighbor who bent the spreaders while I plugged in the wires. This from a person who has trouble making toast in the morning.

I've used my commercial 5-band hexbeam on 6 meters. I'm not sure I really need an antenna tuner to get it to load actually, but I "touch it up" on general principles.

The patern is omnidirectional (no surprise, right?). I really don't notice any difference between the efficiency of the hexbeam and a horizontal loop -- so I took down the loop; one less hunk of aluminium and one less feedine is Good <grin>.

Not that you asked, but fooling around, I've used the hexbeam on 40 and 75. Not effecient at all, but if you have nothing else, it does allow you to play a bit. Loads reasonably well on 30m, by the way.

Hi,
my home made 5b Hexbeam have SWR-2 between 50.0 - 51.5MHz and SWR-1
at 52MHz. Icom-756Pro2 could work without ATU on 6m. Usualy I use
ATU and since May I worked all EU + SU9, ZC4, 7X, 4X.
Computer model shows gain of 5,5dBi and radiation mostly from 18MHz
elements.

2059. measured radiation diagram for 40-20m version

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-07-27 08:52:15 UTC
From: dl7io
Topic: 2059 Message: 2059

Hello,
after the region 1 fieldday contest where we used my beam for 40m/20m
I have tried to measure the radiation pattern and put the
values/diagrams into an excel file. The file is in the file section
in the DL7IO subfolder and called radiation-diagramm-40-20m.xls

I only could measure each band once so the values are not like from a
computer model and there may be some failures due to correct value
reading, correct angles of the rotor, stable transmitting power,
influence of the surroundings etc. But you get an good indication and
can estimate the diagram. Even on 15m where the 40m elements are
radiating you can find a useful diagram.

regards Holger

I have one in design on paper but can not model it yet need eznec 4 to make
computer model to get best results.
75/80m version I have materials but not a computer model.
These figures are just from using the calculator only not an antenna program

From: dl7io
Topic: 2060 Message: 2063

I have done the modeling with EZNEC3. The 40m version played like calculated and 80m should do so as well. The dimensions are in my excel file for calculating the XYZ-coordinates on the first page. Look in the files section, DL7IO subfolder for the file: reflectedw-single-band-koordinate.xls. or take the file reflectedwsingleband.zip. The zip contains also the eznec3 files for all single band versions (10-80m)

I have not enough height for a 80 beam and would need to cut a few trees. But this would bring me in real trouble with my wife. I think as long as you cannot get above 30m with the beam you will get the same (or better) results with a 20m high vertical. And this is much easier to build.

Hi Kevin,

I have a 5btv vertical already up about 25', and it does allright. I still don't have a good idea how big an 80 meter hexbeam might be, so this weekend I will go out in the yard and measure it out. So 80m looks like it will work with a hexbeam? Cool. I also found an antenna called a spider beam which is similar but slightly larger.

I have to go down to my hardware place and see if I can find something that will work for the spreaders since they would be so long on 80. Any suggestions?

2065. RE: [hex-beam] Re: 75 meter hex-beam

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-07-31 01:39:54 UTC
From: Kevin Adam
Topic: 2060 Message: 2065

I ordered some guy rod 3/8" from polygon just for this and my tower install but I won't no if u have any extra or when I would since I'm not on the project currently but I will keep up in mind if I have extra since this is solid rod comes in 8 foot spool min coil size it cost 38 cents foot if you buy 5000 feet I went in with some other haves and we bought 7000 feet total order so I got my 1000 feet extra that I needed. You might look for those old fiber glass Cain poles and pint them because they will rot from sun light fall apart or you could go to a local supplier of gasoline equipment they have a fiberglass pipe that will work to I asked one time it was 1.75 a foot but it comes in 20 + feet lengths and you can glue it together with liquid fiberglass that you get at Napa or boat store. I planned this for the 3/8 solid rod but if call max gain systems he make up a spreader for you not to cheap but not 80 meter beam is cheap to make but this 80 m hex will not cost you an arm and leg to make 200-400 dollars max one other ham ordered spreaders for 10-20 m 90 dollars shipped to him.

I would suggest schedule 40 PVC grey stuff for the center piece one inch diameter
You might try to stay the size of your current one if you could copy your 5bx manual for email it please
N9IWW@...
Also check DL7IO on yahoo groups hex bema he has done a lot the guess work for numbers and information on this since posted a message he made up calculations for 80 to 40 and has offered it for free.
The design I was thinking of covers 80/75 m 60 40 30 20 17 15 12 10 m but if this is so but 10 to 20 only needs 31 feet so I have to move them up the tower to get the right gain this means stacking them on the tower rotate the tower since this 25 g it won't be problem just have to redesign the tower in stall. The 25 g was to support 160 m wire 4 sq so this will be long project.

I have a 4 element 6m yagi mounted about 2.5m under my HX5bi. I have seen little, if any, effect on the hexbeam (or vice versa).

Incedently, the hex loads easily on 6, so I use it for a omni-directional ant on 6.

I'm about to install a 5 band 20-10m Hex in between a pair of 6M 5 ele
yagis. The best thing about the Hex is that none of it's wire elements are
parallel with the Yagis elements, I guess this helps to reduce any interaction.

Has anyone used an aluminium centre support instead of a non insulated
one?, I would imagine there would be issues with stray capacitance on the
feed lines that connect the elements.

From: ct2itz
Topic: 2073 Message: 2073

Dear collegues i am a new menber of Hex Beam group, and very i ama to be part of it. I am not a owner of a Hexbeam..but soon i will if all will go well, i would like to ask you a couple of questions.

1)I am DXer, (iam interested on the HXi 5 bander), can i expect to be able to fight on pile ups together with other collegues on the band?

2) I have a rotary dipole that makes 12..17..and 40 meters, which i am very happy with the performance,,shall i put it down?? because might be bad ralation with the HEX Beam?

3) After customs the Hex beam will the may be 1500 USD with UPs included..do you know if somebody has one to sell in excelent conditions??

4) It the rotary dipole i do have some RFI on neighbours , can i expect more or low TVI and RFI on them..i sow on the web page there is this T4 and T5 RFI supressor..does it really works??

Thank you very much for your help, could you be so kinf to anser to my e mail adress.
Best 73´s

2074. Homebrew hex for 20 meters

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-08-14 00:50:38 UTC
From: W1GQL
Topic: 2074 Message: 2074

Hi, I would like to hear from any group members who have
built a homebrew monoband hex-beam, especially for 20 meters.
I have been modeling them for some time and am now in the
process of putting one up.

I live on the coast of Maine and am celebrating my 50th year
of hamming. Since I retired I seem to spend most of my time
playing with wire antennas and checking them out on 20 meter psk31.

Dave Billheimer W1GQL

2075. 40m hexbeam

> sloaper also at 45'.
>
> de john ko1h

If you want to believe a model, it indicates that at about 80', the antenna has a TOA of 22 degs with an elevation BW of 35 degs. At 40', the TOA is 42 degs and EL BW is about 75 degs. Beam width computed at -6 dB points. Frankly, at 40' you will be some what happy because you will have directivity, gain, and F/B; however, you pleasure will increase as the antenna is raised towards 80'. Will beat a dipole without a question. :-)

Barry W4WB

2077. Re: [hex-beam] 40m hexbeam

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-08-17 17:34:28 UTC
From: Darren G0TSM
Topic: 2075 Message: 2077

I can't comment on 40M, however, the 20M element of my home brew 5 band hex is @17ft. The signals are exactly the same as on a 20M horizontal dipole @40ft. Just scale it up, in theory a 34ft high 40M hex at my QTH should work about the same as an 80ft dipole... Hmmm, now thats worth considering.

2078. Re: 40m hexbeam

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-08-17 18:36:47 UTC
From: dl7io
Topic: 2075 Message: 2078

Hello John,
I probably can give some comments on this because I had to lower down my 40m beam from about 17m (about 54 ft.) to 13m (about 41/42ft).

The difference on 40m is significant. You will DX with the antenna nevertheless but as Barry explained already the toa is much higher at 40ft and the gain a bit less. So every ft. you can get the beam higher helps you a lot.

Last weekend I worked ZL/VK/5H3/YI and others (antena at 41 ft) from here on 40 but it was easier with the antenna 4m higher. ZL is right opposite on the earth for DL and a 18.000 km distance.

For the other bands the hight is okay. Even on 30m it works great at 41 ft.

But the new tower came last week. So before it is winter the antenna will be back at about 50+ft.

regards Holger

PS: By the way, I started to redesign the 20-10m version for bottom feeding like the newer low band designs. The calculations for 20/17m and 20/17/15m are ready.

Here is my best guess as to how the G5RV would act as a hex beam. Since the G5RV acts as several different styles of antenna... depending on the frequency, the results as a hex are going to be radically different for different frequencies. It will probably be most directional at 14mhz since the radiation will be mostly from the wire top (W configuration in the hex), not the ladder line. On the lower frequencies, most of the radiation is in the ladderline, not the top wire so the W reflector won't have much effect, thus no directivity or gain.
And of course the reactance between the reflector and the driven element in the hex will change the electrical length of the "top wire" so it will probably not center around 14 mhz without adjustments.
The G5RV does require a matching network or antenna tuner which the hex doesn't so it is a step backwards there.
I can't really see much potential benifit of incorporating the G5RV into a hex. It seems that a multiband hex would be all around better for space restrictions, and a G5RV puts more metal in the sky for maybe better overall TX/RX but with no usable directivity, but doesn't show to the neighbors as much.

That's my thoughts,

Tim
KC0STO

I can't say for sure, but I think it was something like $450 for both
the rotor and the hexbeam. The catch was it was in Ohio and had to
be picked up. I think it might have been HX5B, not the i version.
I'll let you know if I see anything else pop up there.
73,
Terry, WK0F

It sold for $226.99 and had to be removed from a 35
foot tower in Ohio.

i have a rotating tipover tower with a chanel master rotator for sale.
i will email a picture to interested parties that are located in the
local area (150 miles) of edmonds, wa. this is a pickup item only. i
had a 10 meter 3 element beam on it and it would be perfect for a hex
beam.i am selling the house and can no longer keep it.
the tower consists of a steel base that sits on the peak of the roof
and suports a 18' mast that is guide in 4 directions. at the top is a
hing that allows the mast to tip over. the mast is a alum. tube with
3/4 pipe in it that rotates. the rotator bolts to the base and
conects to the rotating shaft. the rotator is a chanel master and is
included with the tower. $100.00

2092. Tunning the antenna

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-09-05 15:50:47 UTC
From: wa2aae
Topic: 2092 Message: 2092

I have built a Hex Beam antenna and I am having trouble tunning it. The base of the antenna is located about 6' above the ground. At 14.0 MHz the SWR is 1:1 which I believe is acceptable, as the resonant frequency will rise slightly when I raise the antenna. At 18.0 MHz the SWR is >2:1 and my noise bridge indicates that the antenna is resonant below 17 MHz. I've shortened this radiating element, without touching the reflector, by about 4 inches on each end and even though the noise bridge indicates the resonant frequency has moved up I still can not get the SWR down. Any suggestions?

Harvey, WA2AAE

My suggestion is to use an antenna analyzer if available. The other is that if you adjust the director, always adjust the reflector. Also make sure you ends are the prescribed distances apart. One other is the center pole, all coneections are made and the same distance parallel down the pole. There are many other things too numerous to check in this space. Good Luck. Jerry, N5GND

I for one have replied to several Hex questions. I also have give some detailed info on building a hex in the past. My Hex works very well in pile ups and always get through. Granted, It will not work better that a 4 element monobander or large periodic. But for most 3 element multiband beams the Hex will hold its own. Propagation in your favor though is always your best friend. If you have any specific building question, me or several other will usually respond. good luck if you are wanting to build one. From: Bob Nowak
Topic: 2095 Message: 2100

Are the big ones fixed? I don't see how you could
rotate one much larger than 20. How are they mounted?
If I understand the formulas, a 40 would require
spokes at least 18 feet long. Longer wave lengths
would require even longer spokes.

2101. Re: I need help

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-09-06 18:42:08 UTC
From: dl7io
Topic: 2073 Message: 2101

Dear Paulo,

1) I'm using a 5-bander (20-10m) and a 4 bander (40-17m) homemade versions from my QTH which is far more north from you. I got all major DXpeditions. If you can hear the DX you will get it. If you have some PA-support than it takes you only a few calls. But the antenna has only 2 elements per band...

2) Probably it will interfer somehow the beam. Even wire antennas getting the beam to drift out a bit of the main direction. It is difficult to find out without testing or calculating a model. So if you need to estimate it before building/ordering you need to sit down and do some homework with an antenna simulation software.

3) I know that DL7UCX will sell an original HX5B (not Bi). The beam was about 2 years in the air and has been replaced by a big multiband quad. Ask him for details dl7ucx@qsl.net

4) The polarisation of the antennas are the same. I would not expect big differences. Your signal will be about 6 db more or less than before (depending on your direction). Try some bandpass filters at your radio or filter at the problem-devices.

Regarding your question about beam comparision. This is a difficult field because you need two identical installations for a test and most of the people using this antenna have only limited space and therefore they have not the chance to compare 2 setup's against each other. We had during a field day 2 identical towers of about 20m height and about 50m distance between the towers. On top of number 1 we had a A3S beam and on No.2 we had the 40-20m tribander version I made. On 20m we compared both antennas and had no receiving differences between both antennas. But we got reports of 1S-unit plus on the 40-20m beam from DX. We used max. 100W and had good SWR on both antennas with almost the same length of RG213.

BR Holger

Hi Kevin,

I'm not sure what you mean by agreement of the guys, but Traffie published these values back in 1995 in Comm. Quarterly. It is in the Group's file. It is in the Publications folder. A good read.

Dear Ham friends,
Please can anybody help me to find if the Hexbeam will interact with my rotary dipole (12--17--40 meters).
I intended to put the hexbeam at 40 ft high and my rotary dipole 3 meters below,,in the same tower,will the performance of the Hexbeam be afected ??? Can you share your experiences ..it would help me a lot.

Why not just use the hexbeam 10 thru 40 you need numbers see
http://www.dl7io.de/reflectedw/index.html
Here is the information to make it 10 thru 40 even 80 meter to.

Paulo,
the spiderbeam is a very nice and interesting design and a fine antenna. The intention of Con (DF4SA) the developer of the spiderbeam was a light weight and portable contest antenna. So it has sure more gain on the bands as it has 3/4 full size elements. And that's why it is focussed on the main bands.
The diameter of the 20m and up version is about 10m because the driven element is not folded. So the overallsize of the spider is more than 1/3 bigger. The antenna is not that symmetrically built like the hexagonal style and has more wind load. A TV-rotor of the 50US$ class will not last very long here.

The extremely small weight comes from the tiny spreaders. They are made out of fishing pole style fiberglas. You cannot use hose clamps to fix the elements on the spreader.

I have been crossing my spreaders with my car (Van) on a concret base. Nothing happened to the spreader. And Traffie uses a good quality as well. The spreaders are the price building component of the antenna.

Both antennas have their advantages.

regards Holger

From: Tony DiCenzo
Topic: 2108 Message: 2108

Probably a dumb question, but since I have never built an antenna, I will ask it. If the resulting elements are in a flat plane, why bend the spreaders into a cone? WHy not just leave it flat and reduce the stress on the elements and spreaders?

Tony,

Not a dumb question at all. Leaving the spreaders flat would work
ok for a monoband antenna - see the Moxon project at
http://campus.murraystate.edu/org/msuarc/moxon/

Bending the spreaders adds strength and allows the elements for
the various bands to be in their own plane.

I have some pictures in the Photos section under my call.

Good luck,

Michael - kd5wby

2110. Top vs. Bottom Feeding

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-09-14 06:04:37 UTC
From: Dave Simmons
Topic: 2107 Message: 2110

Hi -

I'm in the middle of a homebrew hex project, and was wondering if there is any significant difference between top vs. bottom feeding.

I am planning on feeding from the bottom via 8-10 turns of coax wound in a 6" coil taped to the center support, right below the 10m wires. The elements are fed with #14 solid copper wire, uninsulated, running up the outside of the center PVC post.

I'm planning on using the lengths calculated from files posted in the group's site, using l = 6810/f and the similar formulas.

If there are any advantages from top feeding, or if that affects element length at all, please let me know.

Thanks,

- Dave

Hi Dave,

I made my home brew 5b Hex 2 years ago and it works fine since the beginning without any tunning. You can see it in photo section and in files section is MMANA model. This model doesn't show any significant difference between top and bottom feeding, so I did it with bottom feeding. There are 20cm free space on center support pipe below 10m element and spreaders plate. RG-213 is directly connected to 10m element (twin line), then I did 15 turns over the center support (RF choke) and then coax goes down to the shack. I used few plastic cable tightens at the bottom of the choke to keep it stable.

A week ago I did some inspection on the beam. My spreaders are made from fishing rods (exactly the same like in DL7IO presentation file) and I see some change in painting because of UV, but still in good condition. U-bolts used for TV-rotator are rusty (seller told me they are weather-proof..hi). Wires and ropes are with sillicone insulation and they are in excellent condition, even the colour is not changed. Because of insulation my elements are short by factor of 0,954.

I could say that the weakest point in my case are spreaders.

My beam survived in storm of 120km/h a year ago. Base plate is connected to the rotator with 4 bolts 5mm diameter and 2 of them were broken, but it was the only damage.

Hello Dave,
yes, there is a significant difference between top and bottom loading.
If you like to save your money and may be material don't work with
this formula building a multiband version.
That may work for a single band antenna around 20-10m but not on a
multiband version.
The low impedance feeding line between the elements is active length
for the radiators. If you compare the dimensions of the single band
elements with the size in multiband versions you may see that
difference, especially for the radiators depending on their distance
from the feeding point.
Until today I was not able to model a 5-band design with good gain
and SWR for all 5 bands with bottom loading. 20m makes problems with
the SWR. It is hard to get it under 1:2 at all and I guess that Bob
also had problems with the 20m SWR.
Even if you have no EZNEC... If you download the EZNEC model files
from my website you will find 2packed files in the zip. One is the
model and the second one is a plain text file with comments. I always
wrote the complete dimensions for elements, distances and element
insulators into this file. That may give you some ideas about the
dimensions for bottom feeded versions. You only need to convert the
metric data into your ft./in. dimensions.
regards Holger

I need to correct myself. The feeding is of course not at the 20m element but on the element with the highest frequency or the bottom installed element in the mechanical design.
Sorry for confusing, Holger

I am probably using the wrong terms again. The 6 long flexible radial elements that we attach the antenna wires to. Maybe a better term would be ribs.

looked up the definition of spar and found a couple of interesting ones:

A member of the women's reserve of the U.S. Coast Guard, disbanded as a separate unit in 1946.

A nonmetallic, readily cleavable, translucent or transparent light-colored mineral with a shiny luster, such as feldspar.

Archaic. To fasten with a bolt. [Middle English sparre, rafter.]

and not quite right but closest: Nautical. A wooden or metal pole, such as a boom, yard, or bowsprit, used to support sails and rigging.

also, is there any reason why most implementations run the wire through an insulator on the front of this rib/spar and not around the back?

That you known like spars here is known like spreaders
and in reference of your question i thing is because
is more easy the atachment, but i think this don?t be
an important effect.

HX5Bi antenna at 45 ft performs equally as good as the Lightning Bolt 2 element 5 bander cubical quad at 50ft with 100 watts. Both antennas are on Tri-Ex W51 crank-up free standing tower.
Several tests were conducted and various reports were obtained from distance stations, all confirmed equal signal strength from both antennas.

This situation only occurs at the flatest match of the hexbeam(very close to resonance). If you run tests going to each band edge, especially on 10,15 and 20 meters you will find received signal levels are about 1-2 s-units better on the quad. Its true that the distant station will give you very similar signal reports when above s-5, but this situation degrades rapidly as you approach s-1. With weak signals, the 2 element quad usually will out perform a hex-beam, most 2 and 3 element yagi's based on my experience when I lived in California. Don't get me wrong the Hex-beam is an excellent antenna, and probably the hands down selection when size is the major consideration.

Subject: [hex-beam] HX5Bi Performance

HX5Bi antenna at 45 ft performs equally as good as the Lightning Bolt 2 element 5 bander cubical quad at 50ft with 100 watts. Both antennas are on Tri-Ex W51 crank-up free standing tower.
Several tests were conducted and various reports were obtained from distance stations, all confirmed equal signal strength from both antennas.

John,

Can you kindly explain what you have stated? Hard to understand how the quad hears 6-12 dB better than the HB. Same comment on the "non-linear" performance on the tx side as heard by DX stations.

Its real simple. Ran tests simultaneously like you did. Primary testing was on 17 meters. Tests were nearly identical when switching between Orion, Pegasus and Jupiter. I simply used meter readings for my checks. On my moxon wire beam I had nearly identical results on 17 meters.

Get on 17 meters and work kv2aa Joe in St. Thomas with both antennas between 4:00 and 6:00 PM. He runs a lightning bolt 2 element and you can experience the fade characteristics your self between the two antennas. I stand by my test results in northern California. I haven't repeated these tests hear since the only thing I had up was the 17/15 meter moxon and the hurricane took that out.

From: m0cke
Topic: 2123 Message: 2123

Hi all,

I've been looking back through the archives for a week or so and I'm really interested in building a Hex Beam, so I've started to try and source some materials here in the UK.

The beam will be used at my home QTH only so I guess building it from Fishing Poles will be OK.

I've found the following here in the UK

http://www.tackleshop.co.uk/ProductDetails/mcs/productID/1161/groupID/18/categoryID/152/v/5c0ec454-d6e4-433f-b883-11dfaa1adfc7

http://g4hzj.homestead.com/LocationEA5G4HZJ.html

Both list 4m fibre glass poles for a good price, but when I spoke to one of my local fishing tackle shops they told me that most fibreglass poles actually have some carbon fibre in them now days, if this is true how do I know which are good for the Hex Beam?

I've downloaded most of the files from the Files area and I'm looking forward to building my first Hex which will be a 5 band.

One problem I do have is my tower already has some antennas on which I want to keep, so it looks like I may have to try the offset mounting approach to see what happens!

Any comments or help with building techniques welcome

Regards,

Jim M0CKE

From: Eric S. Johansson
Topic: 2124 Message: 2124

how do you figure out where to attach antenna elements on a spar. is it always where ever the midpoint on that half of the W would reach? the spreadsheet of the 10-30m gave some indications but the inter element feed point looked different from the 10-20m pdf description which would affect the spreader attachment point.

I am also starting to build a 5 band hex beam and have downloaded
the info from dl7io's web site.
http://www.dl7io.de/reflectedw/reflectedw_data.html
If you have also done that you may notice that he gives no info in
regard to the hub size, probably because it is not crucial as are
other specs. I have made mine 12" across measured from 'point to
point' of 1/4" aluminum. That gives you about 5 inches of surface to
mount the spreaders when butted up against the center pole.
I am now wrestling with the practical means of determining
positions to fasten elements to the spreaders in such a way to keep
the antenna symetrical. This is not a project that one wants to rush
if you want to get it right!
Good luck and let me know how you are progressing.
Gerry KC0MSX

I made my hub from a piece of 300mm x 500mm x 6mm aluminium plate. So on mine, from one flat side across to the opposite flat side would be 300mm.

Darren

2129. Single band hex dimensions

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-10-05 11:53:18 UTC
From: W1GQL
Topic: 2129 Message: 2129

In Holger's Excel file "reflected-single-band-koordinaten.xls" he says that the single band demensions for 18.068 are 440 and 427.

The 440 number agrees with the formlua 6262/f found elsewhere in the group files. (When converted from metric to inches.)

The 427 number does NOT agree with the formula 6180/f

To get 427 the formula would have to be 6075/f

I am confused. Can you help me?

Dave W1GQL

PS: Thanks, Holger, for the wonderful work you have done to help Hex Homebrewers. I have a homebrew 20 meter hex that I made using cut-and-try. It is the best antenna I have had in 50 years of hamming.

2130. Getting Parts Together & Center Post

From: Jim Balls
Topic: 2130 Message: 2130

Hi all,

I'm getting all the parts together to build a 5 band Hex Beam.

So far I have

100m 14swg Flexweave
6 x 4m Shakspeare Spearlite 1056-400 Telescopic Poles
12 x 1.75" V Clamps
A 1" Dia Aluminium pole which I will cut in 6" Sections and slice in half
to fit over the Pole to spread out the clamp load
Lots of small Jubilee clips
Some Plastic hose in different sizes
3mm Brass Screws / nuts / washers
Twin lighting cable (maybe try this for the feed lines)
a length of 50mm Grey PVC pipe .. ????
600mm Square of 18mm Eastern Ply (OK for outdoors) which I will cut a 16"
Hex Shape from.
200m 3mm Nylon Lacing Cord

Various other bits of hardware laying around.

OK I think I have enough bits.

Now for some questions.

Will the 50mm PVC pipe be ok for the center post, the outer diameter is
60mm, will this affect the antenna as I see most people use 50mm OD?

Can I fit a SO239 in the bottom of the center post, use coax inside the
pipe to the top and then feed down from the 20M element using twin lighting
cable (I've heard of this being used in the past as a good 75 Ohm feeder).

Once I have the spreaders attached, center post in etc what is then the
procedure for cutting / attaching the elements?

Thanks for any help and advice in this fun project.

Regards,

Jim M0CKE

Is this bare flex weave or insulated?, I've run into problems using insulated wire due to the calculated velocity factor of the wire being different to the actual value. If you are using insulated make sure you either strip off the jacket or get the true velocity factor of the wire.

My center post is 40mm grp tube, this slides down into my stub mast which is 2" aluminium scaffold tube, my hub is clamped to the top of the stub mast. I don't think going to 60mm will make much difference.

>Can I fit a SO239 in the bottom of the center post, use coax inside the

>cable (I've heard of this being used in the past as a good 75 Ohm feeder).

I think you would probably best trying to avoid using a feeder which you know is higher than 50-ohms. Adding a 75-ohm blip on a feed line will no doubt change the SWR a little on one band or another.

>Once I have the spreaders attached, center post in etc what is then the
>procedure for cutting / attaching the elements?

I've used 300mm zip ties wrapped around twice, these allowed me to move the wires around before 'zipping' up tightly.

Hi Darren & all,

Thanks for the replys,

The Flexweave is not insulated so it should be OK, got it from
Nevada at Leicester Rally.

Could you explain in a bit more detail how you are holding the wires
to the spreader please?

I've started with the 20M wires and actually got those fitted today
using Jubilee clips, 2 cable ties, a piece of 6mm clear tubing which
has a piece of the fiberglass pole end inserted as per DL0EI's PDF
file. but i'm finding the Jubilee Clips are a little harsh on the
fiberglass spreaders before they are tight enough.

I did try the 20M before putting any more elements on and I was
hearing some signals with the base of the antenna on a dustbin,
I did try the FT817 on transmitt and the swr seemed to be OK right
at the bottom of the band, creeping up through to 450.

Is anyone using the Hexbeamcalcv3 to calculated there antenna as
this is what I have used to center the frequencies where I want them.

Also do I need to wind a Coax Choke if so what diameter do you
recomend

Thanks again and I look forward to finishing the antenna and getting
it in the air at 45'

Regards,

Jim M0CKE

Hello
Just a question.
I have looked into the Shakespear telescopic poles.
They are made of composite. Does that include carbon and does that affect the antenna?
Would it be better with something out of fibreglass or does it not matter?

From: m0cke
Topic: 2134 Message: 2134

Hi all,

I'm not to happy with the spreader clamping on my Hexbeam project, at present I'm using 4m fishing poles with a piece of half round aluminium around the top half of the pole then using 2 off 1.75" clamps I gently tighten the poles to the center hub but with very little tightening of the clamps I can hear the fiberglass start to pop.

Do I just lightly clamp using lock nuts of do I try and find something about 6" long to put up the inside of the spreader poles, this I have tried but yet to find anything as the poles are slightly tapered, a 1" wooden brush handle is too large.

Any ideas?

Also has anyone used the Hexbeamcalculator v3 from the files area, if so does it perform OK?

Thanks

Jim M0CKE

Jim,
I understand that in using hose clamps to make the attachments of the elements to the spreaders that there is a danger of breaking the fishing poles when tightened down. The same might be the case for attaching the spreaders to the hub with u-bolts. I am placing wood dowel material inside in both situations. It was quite a slow process though as I turned my dowels on the turning lathe with a slight taper and made to fit at predetermined postions on the spreader. I made the dowels about 5 inches long so I had a little flexibility when finally attaching the hose clamps in their respective positions. Also, one needs to start inserting these protective dowels at the small end section and insert it into the next larger size of the pole before treating that larger section with dowels. If your concern is to only protect the pole at the hub that should be quite easy. Although I custom-turned mine, I found that a standard size dowel came close to filling the void. One could wrap a few turns of masking tape on an undersized dowel to do the job. (Incidentally, I also inserted a small strip of sheet aluminum between the u-bolts and the fishing pole for additional protection from crushing the the fiberglass at the hub.) Good luck with your hex beam project!

2137. Impedance & SWR

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-10-16 18:32:45 UTC
From: m0cke
Topic: 2137 Message: 2137

Hi all,

I've just built a 5 Band Reflected W for use at the main station here. The beam is up at about 45' When I test the beam with a MFJ 259 i get the following results, these are the lowest dips in SWR

20M - 14.205 Mhz R=56 X=14 SWR 1.3
17M - 18.112 Mhz R=25 X=9 SWR 2.0
15M - 21.100 Mhz R=24 X=5 SWR 2.1
12M - 24.861 Mhz R=100 X=41 SWR 2.5
10M - 28.285 Mhz R=50 X=50 SWR 2.5

Any ideas why the impedance is out on all the bands except 20M?

I'm feeding the antenna with a short length of Mini RG8 (connected to the main RG213 feed)which has a coax choke of 6 turns 4" diameter at the base of the antenna, I'm feeding at the top and using 10A DC cable (black & red figure 8) for the feedlines.

Could it be the feedlines are not of a heavy gauge?

I have taken care with the Driver / Reflector tip spacings and they are within a couple of MM.

The antenna was built using the spreadsheet V3 from the files area, I did note that the elements were longer on most bands except 20M in comparison with the DL7IO PDF file.

Thanks for any help

Regards,

Jim M0CKE

Please post your driven element lengths for each band. This will allow some of us to compare our hex beams to yours. Also, please advise us of wire size, material, and if it is insulated or not. The other item is the type of spreader you are using. Is it polyester fiberglass pultrusion or a graphite fishing pole. The carbon graphites tend to affect the higher frequencies more. Also, I have had much better results with ferrite choke type baluns made up off a string of ferrites on the feedline coax OD. Palomar Engineers has a nice setup for about $8.00 US

One of the UK retailers (cant remember which one) said that the red/black cable which is used for rig power leads is approx 85-Ohm. I use 6mm cable for my feed line between the elements.

2140. Re: Impedance & SWR

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-10-17 07:06:26 UTC
From: m0cke
Topic: 2137 Message: 2140

Hi John / all

Thanks for the reply,

OK the spreaders are Shakespeare Spear-Lite 1056-400 telescopic poles, so I guess they must me Carbon Graphite although at the price of £2.99 I thought they would have been fibreglass. I've just looked on the Shakespeare.nl website and for construction material it just states Mixed.

The center pole is grey PVC and the OD is 60mm

The feed is spaced as per DL7IO's PDF file, distance between the Hot & Cold connections is 1.5" measured around the circumferance of the center pole

The band feeding wire is outside the pole and each wire is 28/0.2mm CSA is only 0.79mm .. I can now see that I need to change this for at least 4mm.

Element connection screws are 3mm Brass 25mm

Element wire is 14 Gauge Flexweave un-insulated

Element lenghts, Spacings are:-

Frequency (Mhz) 28 Inches half length
Driven Element Length 216.84 108.42
Reflector Length 220.42 110.21
Driven Element Spacing 3.58
Reflector Spacing 2.28
Over All element spacing 5.09
Spreader length 54.21

Frequency (Mhz) 24 Inches half length
Driven Element Length 248.19 124.1
Reflector Length 252.29 126.14
Driven Element Spacing 4.1
Reflector Spacing 2.61
Over All element spacing 5.82
Spreader length 62.05

Frequency (Mhz) 21 Inches half length
Driven Element Length 290.82 145.41
Reflector Length 295.62 147.81
Driven Element Spacing 4.8
Reflector Spacing 3.06
Over All element spacing 6.82

Spreader length 72.71

Frequency (Mhz) 18 Inches half length
Driven Element Length 341.44 170.72
Reflector Length 347.07 173.54
Driven Element Spacing 5.64
Reflector Spacing 3.59
Over All element spacing 8.01
Spreader length 85.36

Frequency (Mhz) 14 Inches half length
Driven Element Length 435.21 217.61
Reflector Length 442.39 221.2
Driven Element Spacing 7.18
Reflector Spacing 4.58
Over All element spacing 10.21
Spreader length 108.8

I hope the above comes out OK on your email / browser.

I have tried the antenna, it is better than anything I have at the moment, but It looks like the performance on 20M is better than the other bands, all bands show F/B of about 10db and lots of F/S.

I'm interested in the ferrite choke type balun, Is there a reference for this type of balun and any idea where in the UK i can get the ferrites?

Thanks for any comments / help.

Hi Darren / All

What 6mm cable did you use, did you strip out some Twin / Earth (6242Y) or did you use Conduit Wire, something like 6491X or was it something else?

Thanks,

Jim M0CKE

Yes 6mm conduit wire, I stripped back the insulation where the elements connect then soldered the elements to the feed line and then re-insulated the joints with self amalgamating tape. The whole assembly was then zip tied together and then zip tied to the main support. I love zip ties!

The choke balun should be made of type 43 mix ferrite toroids with an inside diameter that matches your coax I.D. Use about seven or 8 of them. They usually come with an I.D. of about .250 or .500. Just bunch them together on the coax and use heat shrink tubing to hold them. The most economical place is to get them here in the states is palomar-engineers.com. I am sure these toroids are available all over europe.

I am still digesting your setup so it will take me a few days to figure out what you have at your qth.

2144. Re: [hex-beam] Re: Impedance & SWR

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-10-17 17:47:23 UTC
From: john labutski
Topic: 2137 Message: 2144

Error in my last email. I should have said the O.D. of the coax should match approximately the I.D. of the toroid. In other words 1/2 inch OD coax including insulation gets put thru a toroid with a 1/2 inch ID. Guess I will have to start proof reading my emails.

John

Subject: Re: [hex-beam] Re: Impedance & SWR

The choke balun should be made of type 43 mix ferrite toroids with an inside diameter that matches your coax I.D. Use about seven or 8 of them. They usually come with an I.D. of about .250 or .500. Just bunch them together on the coax and use heat shrink tubing to hold them. The most economical place is to get them here in the states is palomar-engineers.com. I am sure these toroids are available all over europe.

I am still digesting your setup so it will take me a few days to figure out what you have at your qth.

Subject: [hex-beam] Re: Impedance & SWR

Hi John / all

Thanks for the reply,

OK the spreaders are Shakespeare Spear-Lite 1056-400 telescopic poles, so I guess they must me Carbon Graphite although at the price of £2.99 I thought they would have been fibreglass. I've just looked on the Shakespeare.nl website and for construction material it just states Mixed.

The center pole is grey PVC and the OD is 60mm

The feed is spaced as per DL7IO's PDF file, distance between the Hot & Cold connections is 1.5" measured around the circumferance of the center pole

The band feeding wire is outside the pole and each wire is 28/0.2mm CSA is only 0.79mm .. I can now see that I need to change this for at least 4mm.

Element connection screws are 3mm Brass 25mm

Element wire is 14 Gauge Flexweave un-insulated

Element lenghts, Spacings are:-

Frequency (Mhz) 28 Inches half length
Driven Element Length 216.84 108.42
Reflector Length 220.42 110.21
Driven Element Spacing 3.58
Reflector Spacing 2.28
Over All element spacing 5.09
Spreader length 54.21

Frequency (Mhz) 24 Inches half length
Driven Element Length 248.19 124.1
Reflector Length 252.29 126.14
Driven Element Spacing 4.1
Reflector Spacing 2.61
Over All element spacing 5.82
Spreader length 62.05

Frequency (Mhz) 21 Inches half length
Driven Element Length 290.82 145.41
Reflector Length 295.62 147.81
Driven Element Spacing 4.8
Reflector Spacing 3.06
Over All element spacing 6.82
Spreader length 72.71

Frequency (Mhz) 18 Inches half length
Driven Element Length 341.44 170.72
Reflector Length 347.07 173.54
Driven Element Spacing 5.64
Reflector Spacing 3.59
Over All element spacing 8.01
Spreader length 85.36

Frequency (Mhz) 14 Inches half length
Driven Element Length 435.21 217.61
Reflector Length 442.39 221.2
Driven Element Spacing 7.18
Reflector Spacing 4.58
Over All element spacing 10.21
Spreader length 108.8

I hope the above comes out OK on your email / browser.

I have tried the antenna, it is better than anything I have at the moment, but It looks like the performance on 20M is better than the other bands, all bands show F/B of about 10db and lots of F/S.

I'm interested in the ferrite choke type balun, Is there a reference for this type of balun and any idea where in the UK i can get the ferrites?

Thanks for any comments / help.

2145. Hex Pac Portable at Jamboree on the Air

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-10-18 16:44:43 UTC
From: sx88ht20
Topic: 2145 Message: 2145

Another happy ham outing with the Hex-Pac portable! Troop 204 / Pack 702 in Marietta, Georgia, hosted a Jamboree-on-the-Air activity last Saturday. We set up the antenna with the 20m element on the roof of one of the classrooms at church (about 45 feet in the air), with a second antenna (dipole) for 40 meters. Rigs used were Mark-V and FT897.

We had a terrific signal on the air for the entire day. Many stations commented on how strong our signal was. Over 80 people attended our JOTA event, with a few of the Boy Scouts and parents taking an interest in getting their ham ticket. It is so important to have a good signal when operating for guests or a demonstration. I have used the portable Hex-Beam over and over and been very pleased with the results.

Hi John / all

Thanks for the info on the Choke Balun, as of yet I still cannot find the beads in the correct mix here in the UK, I've tried searching the net with no luck, Maybe I need to fin d a company that will ship to he UK from the US.

Thanks for looking through my antenna details, It's certainly working as I' getting some good reports, This weekend I intend to remove it from the tower and replace the feed lines, I have now made up some parallel lines with 10mm2 cable, i've stripped the insulation at the feedpoints by about 5mm and soldered on the connecting lugs at right angles to the lines, this should keep the lines together from top to bottom.

Also I'm using an offset mount, the main rotator stub pole is stainless steel and runs between the cold leg and reflector about 1' away from the center of the Reflected W.

Below the beam I have 4 Microwave beams, each 10' long from aluminium these are about 2' below the hex and on the top of the stub mast I have a tri-band vertical 6/2/70 and the radials are very close to the top of the hex.

I in ted to put in a longer stub mast to help to move the antenna apart.

Would you put the Microwave stuff above or below the Hex .. ?

Thanks,

Jim M0CKE

2147. Re: [hex-beam] Re: Impedance & SWR

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-10-19 11:32:16 UTC
From: john labutski
Topic: 2137 Message: 2147

I think you solved your problem yourself. Two feet is insufficient separation for your microwave beams. Wire beams are much more sensitive to a mass greater than itself such as those beams. In my case I have a screened in pool enclosure with an aluminum support structure. This enclosure was about 3 feet too close to one of my wire beams (a tuneable moxon) experiment. It drove me nuts because rotation of the beam would affect the swrs. Moving the beam 3 feet further away from this structure made all the difference in the world. Since the hexbeam is very light, I would increase the distance between the hex and your microwave beams. Just calculate how much by looking at your angle of radiation for the hexbeam and provide an additional foot or two The further away from the planes of the hexbeam the better. The same goes for your radials for your vertical. I do not know how many radials you have but changing their physical position with respect to the elements of the hexbeam may allow you to keep them in the same height. If it was me, I would lower the hexbeam to 40 feet and raise the other antennas. Hexbeams work great even as low as 30 or 35 feet. Although if you run more than a couple of hundred watts, you may have rf problems with 30 feet on 20 meters.

John

Hi all,
I've just discovered hex-beams and I want to build one of these antennas.
what are the formulas/spacings etc?
also, what materials are best with which to build a hex-beam?

thanks es 73 de Brett/KC5BEZ

Brett,

You can find your answers by reading the material contained in the
Files section of this site.

John,

Type 43 isn't the material of choice for the RF choke. Type 77 is far better. Type 31 is also an option, but its Curie temperature is much lower than the Type 77 (or 43). Yes, some companies sell the 43 material for this HF application, but they should know better.

Thanks for the input Barry. I will have to try type 77. The type 43 has always worked well for me. I must say,however, this old dog is always willing to learn new tricks. RF in the shack has always been a common problem among hams and your inputs are very welcome.

FB John. I use the Amidon FB-77-1024 beads and have found about 6 is
adequate. These slide over the RG-213 (0.5" I.D.).

2153. Feedline separation

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-10-23 16:00:29 UTC
From: gerry_schjelderup
Topic: 2153 Message: 2153

Hi all,
Help! I have begun assembling a 3 band hex beam for 20,17, and 10 meters. Have thus far only installed the 20m element. I am using insulated #14 stranded wire and have reduced element length by 6" from normal specs. But my swr readings are too high to corrected by element length adjustment. 3:1+ Is the feedline separation on the center pole a factor in influenceing my swr? Or can there be another factor making my swr readings so high?
Gerry KC0MSX

2154. Re: Feedline separation

Topic: 2153 Message: 2154

Hello Gerry,
where did you take the dimensions for this version (20/17/10m)? Have you done some calculation for this 3 bands?
What are the dimensions you will use?
How are you feeding (at 10m or at 20m element)?
What are you using for the feeding line?

In multiband versions you have you install all wires. You will not have success installing one band trying to tune it. This will work but measuring with the second band installed you will have totally different results and will need other dimensions. And continueing with band No.3 you have to change all elements again.

You cannot use 5-band diemnsions and install it without 15/10m. It will not work properly.

Regarding the feeding line. It is a low impedance line. To get a low impedance you need the wires as close together as possible. The best is to fix them with cable strips (hope it's the right word). As more you separate the wires as higher the resistance of the feeding system will be. Remember a chicken leader has a couple of hundreds Ohm.

If you have any antenna model please let us know.

regards Holger, DL7IO

Hello Holger!
Thanks much for the speedy response! I fear that I may have to start all over! I started with the intention of building the 5 band reflected W beam that I believe you had posted on the net. Unable to conveniently find bare wire, I elected to make the elements shorter on the basis of the suggestion 10 to 15 cm shorter. Assuming the 20 meter element at 217.32 would be reduced to 211.34, I came up with a ratio of change, .9725 and applied it to all element dimensions, and reducing the tip space also using the same ratio. It then was not until I had obtained my fishing poles for spreaders that it seemed the large spreader diameter near the hub resisted curving and would seem to have caused my lower band elements to be too close together that I then decided to do only 3 bands to allow more element separation between bands.
I apparently will need to start all over and have thus far only cut the 20 meter elements. I used a piece of RG8-M coax split open for the feedline, keeping the shield about 1-1/2" from the 'center' conductor. I know now that was a big mistake, but if the lines were brought close together would the RG8-M be adequate. It was the only coax available locally. Obviously I will need something better for coax to the radio. Incidentally, I am feeding the 20m element.
I would like to stick to my using insulated wire since I have it, but otherwise what is your best advice? I would go back to a 5 band version if I can make it work. Thanks much!
Gerry KC0MSX

From: Darren G0TSM
Topic: 2153 Message: 2156

This goes back to insulated wires, PVC covered wires all seem to be different, they do not have the same insulation thickness and different additives are used to make them fire retardant, flexible etc.
There seems to be only one method of finding out how much to allow for the insulated jacket if you can't get the technical info from the wire manufacturer, you make up a dipole using insulated wire, say for 10m, you measure the impedance over the band using an analyser and then you strip the insulation, recheck the length incase you stretched the conductor while stripping , put the antenna back in exactly the same position and then see now much up the band the resonant frequency has shifted. It is then easy to work out your 'shortening factor'
By guessing the velocity factor of the wire you could be a little out, I guessed at 0.975 which seems to be what everyone uses for pvc wire but my 1.5mm(csa) wire with 0.7mm jacket comes out at 0.96, Not a lot in it but 1.5% is still enough to shift the resonant frequency of my hex by 400KHz on 28MHz.

To save a lot of headaches, use bare wire and if it still doesnt work blame Holger ;-)

Topic: 2157 Message: 2157

Holger, you really have me very curious! What is "Chicken leader"?
I never heard that one and I like it!!! I wonder if it might be
what we call "zip cord" here in the states?

Dave W1GQL
Proud owner of a wonderful homebrew 20/17 Hex that is the
best antenna I have had in 50 years of hamming!

2158. FAQ file

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-10-24 18:11:34 UTC
From: W1GQL
Topic: 2158 Message: 2158

I am visiting with my sister-in-law in Olympia Washington. She has a very fast cable connection to the web. Since I only have a 26.6 dial up connection at home in Maine, I have taken advantage of her fast connection to read all the group's postings since the beginning.

Having read them all in a couple days, I have noticed that a number of homebrew questions are repeated over and over. Very often the person asking the question is told to check the files sections for answers. I know from experience that digging through those files can be frustrating, since some of the files refer to multi-band versions of the hex and others to single band versions.

What I propose is that we create a FAQ (Frequently Asked Questions) file that we can refer people to. I would be happy to create such a file and maintain it. It's not that I know all the answers, but that I have time and am willing to ask people who do know how to answer them.

What do you think?

Dave W1GQL

Hello Gerry,
will try to answer your questions in your text.
By the way...the FAQ idea is very good in my eyes. We should start with the comments EI7BA already made on his page. There are a lot of FAQ's collected. Even I decided to make a redesign of the 5band-pdf-files with some more often asked details and dimensions for other beams as well.
regards Holger

The next posting offers a good possibility to find out the ratio of change. I guess you can take any kind of not insulated cable to get the difference in the length and you don't need to remove the insulation from the cable if the diameter of the wire is the same.

When I started with my designs I could not calculate with EZNEC and wire insulation. But without calculation I was not able to get usefull results. I finally bought "some" miles of noninsulated wire. The only available source to me was a local manufacturer and he asked me how many tons of copper wire I would like to buy... There will be some wire left for my kids as well ;-) Later I found that the noninsulated wire also is much (about 50% I guess) lighter and easier in the handling than insulated wire.

Don't do this! Install all bands. There is a good chance that even if the elements are closer together you will get all bands working fine.

IF you have problems with 10/12m to get them working, choose 12m for optimization. For 10m you easy can get a 3 ele CB beam for a couple of bugs and change this.

> I would like to stick to my using insulated wire since I have
it,
> but otherwise what is your best advice?

I was thinking about the feeding line along the center hub, between the different elements. Again use wire of high diameter 4-6mm² at minimum and install the wire as close together as you can. The distance between the wires is making the impadance of the cable. As bigger the distance as higher the impedance and we call this feeding system "low impedance line" which means as close together as you can.

Here comes the terminus "chicken leader" from which is one by one translated from the German. One of the last posting had this question. The high impedance lines of 300/400+ Ohms we build/t ourself from wire and plastic or wooden sticks to hold the wire in a definite distance is called "chicken wire" feeding system in German.

I would go back to a 5 band

From: Mark Robinson
Topic: 2158 Message: 2161

Some of is have no options. There is no cable here or dsl. I am lucky that I can get a 46K connection but I have friends who can barely hold 26K on their phone line. I have been waiting for dsl for over 5 years now. Finally Nextel are offering high speed wireless in this area. I am on the fringe of reception, so I am not sure if that will work but it's worth a try. Maybe a hexbeam will help me hi hi

Mark,

A FAQ is fine. I suggest that it be maintained in the Database
Section of the group. Contact me direct and I will explain how to
use the database for this purpose. I have built several others in
different groups. Would be pleased for you to build and maintain it.

Darren, Thanks for the suggestion of trying a sample stripped test
wire the determine a shortening factor for insulated wire elements.
Also think a FAQ suggestion could be useful and convenient.

Holger, you really have me very curious! What is "Chicken leader"?
I never heard that one and I like it!!! I wonder if it might be
what we call "zip cord" here in the states?

Mike,

Huehnerleiter does "directly translate" into chicken leader if one uses Babel Fish. Forgive me, but my German skills are very rusty from decades of non-use. However, if I recall correctly, Huehnerleiter was/is used in some cases to describe a walkway (often raised above the ground) comprising parallel supports (such as logs) with planks between them. Rather looks like a feedline with the supports being the conductors.

In English for this purpose, Huehnerleiter I believe would best translate to open-wire or window feedline. As you noted, the feedline is symmetric or, more commonly called, balanced. Impedance ranges from generally 300 to 600 Ohms depending upon the construction. Typically, window feedline (so called because some of the insulation between the conductors is cut out to form openings or window with the rest left to form separators ... also done to reduce the weight and wind load) is 450 Ohms while the stuff with the wider spaced rods is 600 Ohms.

73,
Barry W4WB

2167. Update on 5 Band Build - Strange Happenings

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-10-25 07:42:47 UTC
From: Jim Balls
Topic: 2167 Message: 2167

Hi all,

Over the last few weeks I have built and tuned my Home Brew 5 Band Reflected W. I was having trouble with the matching so I built a new feed line from 10mm2 cables which are tied together and tabs soldered on at the correct distances for feeding the elements, this has cured the impedance problems but I'm now struggling to get the antenna SWR acceptable on all bands.

My hex is installed on my 4 section 45' wind up / tilt over lattice mast, the stub mast from the rotator is 2" Stainless Steel and I have made an offset mount, when on the tower the stub mast runs up between the cold side and the reflector, the same as the Coax.

I've removed all other antennas from the tower at present except for a tri band vertical which is about 2' above the top of the hex.

I spent most of Sunday trying to fine tune the elements for an acceptable SWR, what I have noticed it that height above ground affects the SWR in a big way, if I only have the antenna at about 30' then the SWR is OK on most bands except 15m, for some reason this looks short in length. If I wind the antenna up to about 50' then the SWR is out on 20M, 15M & 12M .. 15M still looks to be to short and 12M looks long on the MFJ analyser.

The ground below the tower has a 10 x 8' garden shed and at the back about 9' from the tower mounting there are some Hawthorne bushes about 15' tall and a bit further away is a tree which is about 20' tall .. I guess these must be affecting the SWR?

Do you think I should try optimizing the height above ground for best SWR on most bands then just tune the odd ones or do I go for maximum height?

Maybe the Triband Vertical which has radials on, one long one for 6m is affecting the 20M as this is over 2:1 at it's lowest when it's at 50' but at 30' it's 1:2 at it's lowest which is about 14.030 ... strange or what?

I'm still using the Coax Choke 6 turns of RG Mini 8 wound on a 4" former (mid section of a Ocean Spray White Cranberry Juice bottle !!)
as I cannot source any ferrite beads here in the UK .. is the 6 turns correct for this coax?

I'm having some good success with the antenna, just calling CQ on 10M results in many stations calling me on Sunday Afternoon with good reports, this morning I had the tower 30' because of the wind and I worked Dakar on 20m second call with most of Europe calling, so it definitely works ..

Any advice on the tuning or checking for faults would be most appreciated.

Oh and has any tried feeding from the bottom using external feedlines, if so what are the feedline lengths below the 10m element where the coax would be connected?

This is a most interesting and sometimes frustrating project!

Regards,

Jim M0CKE

2168. Re: FAQ file

What a brilliant idea, I've scoured the group and still I'm finding questions to ask which may have been covered but actually finding the message again from the thousands takes a while especially if your not sure what words to put in the search

Using the Database on the group is a very good idea.

I've actually read this after my last posting about my attempt at a 5 Band hex which I'm still struggling with .. if you have anwsers to a couple of the questions then put them in the FAQ.

Thanks for a great group and a great project!

Regards,

Jim M0CKE

2170. Still having problems & Comparison of Home Brew Design Dimensions

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-10-27 17:23:19 UTC
From: Jim Balls
Topic: 2170 Message: 2170

Hi all,

I'm still struggling to get my home brew beam to play properly, So I thought I would create a spreadsheet with the dimensions used by DL7IO, LZ2BE and from the formulas in hexcalcv3 to try and understand why I have a problem.

I originally cut my elements and tip spaced as per the hexcalcv3 file, but used the center post feed spacing as per DL7IO, after playing and getting very mixed results I decided to set the element lengths and tip spacing to DL7IO's PDF, this was better but still mixed results and not the SWR curves or expected Impedance at lowest SWR. SO Iâ□□m looking deeper now, Maybe I need to strip back the insulation on the 10mm2 feed lines to get them closer together. I'm also going to test my 100' of feed coax to make sure there is no fault on this. I'm also waiting for some type 77 ferrite beads to make a better choke than the present 4" dia 6 turn RG213 choke.

I have uploaded some picture to the Photo's sections, maybe someone could comment if they can see any problems, especially with the low impedance feed.

Anyway back to the table If you are interested it should be shown at the bottom of this email, I hope it's displayed OK as I know some email systems mess up this sort of thing, I have calculated the difference in Reflector / Driven lengths as CM and % as a comparison for each system.

LZ2BE's is bottom fed at the 10m element and the dimensions are from the MMANA file
DL7IO's is top fed at a point 4.5cm above the 20M element and the dimensions are from his PDF file
Hexcalcv3 is top fed at a point 4.5cm above the 20M element and the dimensions are from the hexcalcv3 Spreadsheet.

I'm interested how the LZ2BE has a reasonably constant difference in % of lengths yet the DL7IO differs quite a bit, if you look at the difference in lengths on the 17 / 15 / 12m bands they are

all 6cm.

I'm not faulting the work compiled by these knowledgeable people I just need to try and
understand why the differences and the results caused by the differences.

I have noticed that the hexcalcv3 makes the 17M and 12M element much longer than in the DL7IO pdf.

I couldn't get the table to display properly so I've created a folder in the Files area of the group called Calculation Comparisons, in here is the Spreadsheet I've been messing about with, take a look at the comparison sheet.

Any thoughts on the results shown in the table?

Thanks

Jim M0CKE

Hello Jim,
before you installed the beam in his position between the other antennas, have you measured the SWR-values at a hight of about 3-4m? If yes what were the results?

I guess in a former posting you also wrote that the antenna changed it's values while moved to the final position. That is unusual to me. My beams almost don't change SWR while changing their height. As I have a telescope tower 3-15m their is no significant change of the SWR-values even for the 40m beam. The reason in my opinion is the coupling in the magnet field component because the wires are so close together in the middle and at the ends. So the influence of the electrical field component is not like for yagis where the coupling between the elements is in the electrical field. Here of course you have a strong influence of the earth/ground which can be seen while changing the height. If you can compare to a yagi (I had tribanders for tests) you will see or better hear that our beams are more quite. This also confirmed me in my opinion. It acts more like a closed loop or a magnetic loop. So if the SWR is changing a lot that could be the result of the surrounding antennas or other metal parts that are close to the beam (e.g. the mast moving along the center post to hold the top antennas). I have no experience with an installation like yours but if the SWR changes a lot I'm assuming an external influence by the other antennas or metal beams.
regards Holger

2172. Re: Still having problems & Comparison of Home Brew Design Dimensions

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-10-28 07:35:10 UTC
From: m0cke
Topic: 2170 Message: 2172

Hi Con,

OK What I have done is stripped off nearly all the other antenna's except for the 6m/2m/70cm Triband Vertical which is above the antenna, a small 70cms beam which is about 2m below the antenna and a small 2.3ghz antenna which is about 1m below the antenna.

Because of my lack of garden space and overhead antenna cables it's impossible for me to test the antenna without installing on the main mast, so tests were not done prior to installing.

I have taken a picture of the beam as it is installed now so you can see, I have put this in my Pictures Folder on the group.

Also I have put a spread sheet with my SWR / Impedance findings in the Files area in the M0CKE folder (These can be deleted after you have looked if they are of no use).

I will test today on the height problem, I think since I have changed the feed coax from RG Mini 8 to RG213 the problem of the SWR changing with height has gone, I will update you later should the WX be ok.

When I'm trying to tune the bands I'm folding back the element wire at the ends and taping it to the element then inserting the folded end into the connector block, I know this isn't ideal but it's the only way I could think of trying to change the resonant frequency without cutting the wires incase I went too short .. is this OK?

Please take a look at the pictures and SWR spread sheet and give me your comments.

Thanks for your time, problems are all the fun of a great project!

Regards,

Jim M0CKE

Hi Jim,

I think your were writint to Holger rather than Con of the
Spiderbeam. :-)

Somehow in our private emails, I missed that you have the antenna
above the HB. FWIW, this has been observed to be a problem for some
people. One of the issues is how you support the vertical, what it
is made of, spatial relation of the support wrt the HB, etc.

I note that some cases work and others don't.

73,
Barry W4WB

Jim,
If you like I will discuss it with Con to find out his opinion ;-)
We know each other well and from time to time we have long telefon
discussions about antennas, calculations, materials and even other
things.

I had a look on your SWR curves. It does not look to strange to me.
Most of the bands seem to be to long. That is better than otherwise...
Only 15m is to short for about 5cm. Please shorten only the radiator.
Do not touch the reflector. The reflector is most important to get
gain and the radiator has most impact on the SWR. I'm not sure how
difficult it is but the best way would be to change one band and
check and compare all other bands with the values you got before. In
the model the changing of one band influences also the next bands and
this is as more as closer the wires are. So 12m tuning has be done
very carefully.
17m is about 0.8% to long about 6-7cm.
15m is about 1.6% to short about 5cm
12m is about 1.2 % to long, about 3cm.

The constant SWR on 20m might be a result of the top antenna.
10m looks fine to me.

Keep us informed!

Holger

2175. Re: Still having problems & Comparison of Home Brew Design Dimensions

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-10-28 20:01:08 UTC
From: m0cke
Topic: 2170 Message: 2175

Hi Holger ... Sorry, I'm also getting parts togethter to build a Spider Beam for another QTH.

OK I've spent most of the day tuning the antenna and I have taken note of your comments on not altering the Reflector, So now I ahve most bands with a reasonable SWR except for 15M, What ever I do to this band it will not work. I've uploaded the SWR data into the Files area again m0cke refW SWR V2, Take a look please.

I have tried shortening upto as much as 10cm on each leg and I have tried lenghtening as much as 15cm on each leg, still no joy, It does move the SWR but not very far.

I notice there are 2 sections around 15M which are dipping, One high One low but I'm guessing these are interactions of other elements as the altering of the lengths doesn't make mush difference to either dip. These are shown on the SWR spreadsheet as I have done a broadband sweep from 20Mhz to 23 Mhz so you can see my problem.

Any ideas anyone?

I have stripped off all antennas now, but I'm still using the offset method of mounting as when I get the antenna close I will try adding back the other antenna's to see what the effects are.

Thanks again for all the help from the group, it would be very difficult without!

Regards,

Jim M0CKE

2176. Re: Still having problems & Comparison of Home Brew Design Dimensions

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-10-29 08:32:50 UTC
From: m0cke
Topic: 2170 Message: 2176

Hi Holger.

Raining here today so I expect not to get anything done :-(

So I've complied my measurements into a list for you to look at,
this corresponds with the latest SWR curves for the antenna at 30'
The 15M elemets are set as I originally cut them from the hexcalcv3
spreadsheet, all others have been altered for SWR, I need to
lengthen the 10M band again.

Band Reflec Driven Ref-Tip Ref-Dri Ref>Dri Ref>Dri
Space Space

20M 566 552 11 28 14 2.51%
17M 431 419 9.0 22.5 12 2.81%
15M 378 372 8.0 20 6 1.61%
12M 311 301 6.5 17 10 3.31%
10M 284 276 6.0 15.5 8 2.68%

I had the whole antenna down yesterday and checked all the driven
element connections, solder joints on the feedlines etc and found no
problems .. realy confused with the 15M band problem!

Regards,

Jim

After weeks of playing I finally found the problem .... COAX!
I had a run of H100 up the mast which seems not to like HF .. lol
I swopped it out with a run of RG213 and all is well.

I've put the latset SWR results in the files area again under my
folder, if you would take a look please Holger and report and
adjustments you think I should make, although SWR is now good on all
bands I think the low SWR may start a little low on some bands, I
think I read somewhere this affects F/B and gain?

Thanks for all your help, just in time for CQWW!

Regards,

Jim M0CKE

Hi Jim,

Glad you isolated the main problem. Declare vistory and enjoy the contest. However, 10 m looks like it still needs some attention.

A good test is to listen to some of the 18 beacons (http://www.ncdxf.org/beacons.html) and check your F/B performance on each band.

73,

2179. Now it's working How do I?

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-10-30 11:47:55 UTC
From: m0cke
Topic: 2179 Message: 2179

Hi all,

OK Now the Homebrew beam is working I need to understand how the F/B & Gain changes when tuning through the band.

Also what effects have the Tip Spacings have on the performance, although mine are set exactly to Holgar's information.

What affect does the length of the Reflector have on the F/B ad Gain?

What affect does the difference in length between the Driven and Reflector have on F/B and Gain?

Reason I'm asking is once I've had time to evaluate the performance I may wish to try altering the F/B should I think it seems low.

At present it seems to be working very well and for it's size it's excellent!

Thanks for any replies.

Jim M0CKE

Hi Paul,

My problems were not the beam as I have found out, if I had used the coax i'm using now I would have had the antenna working a couple of weeks ago .. saying that it's working well and has very good bandwidth, be carefull of the MA5B as I've heard the bandwidth is small on 20m also it's only a Dipole on 17m & 12m.

I would still build this again even after all my self inflicted troubles .. lol

OK been working some of the CQWW today getting through big pileups with the beam .. It works!

I've ask the questions because I want to know what affects the F/B and Gain .. all interesting to me.

I also have anoth local who is looking at building one and is comming over soon to take a look.

If you want to pop over just drop me an email and you can come over i'm only 1/2 hr frrom Pbrough.

See you on 40

Jim

A narrow bandwidth is no good to me ,who's well into hifi audio, W&S seem to think there the answer , another they are trying to sell me is a diamond CP6 vertical, never heard of them, Ive got to doo something soon ,she who must be obeyed at all times , doesn't like to see the wires dangling down. Thanks for the offer I may well do that if i can't decide which way to jump, mind you this is my chance to buy a field force 12 mmmm

Is there any reason two smaller hex beams cannot be stacked? I want to stack a 10-15 hex and a 20m hex on one mast. since the elements are stacked in the 5B hex, I believe it will not cause undue interference. But will appreciate any insights.

Yes Tony, they can. I suggest you speak with Mike Traffie since he has done stacking a number of times.

Yes you cann stack Hex Beams if you search the web ou will find photos of this been done. With the tower.

Hello Tony,
sure they can be stacked on a tower. I have been thinking about stacking 4 beams for 20-10m. This doesn't look to difficult by the mechanical problems and has an easy feeding.
But I'm not sure if we are talking about the same. If you mean to build your 15-10m wires into the 20m antenna that will probably not work that easy. Here you will have to do some calculations with an antenna simulation software before starting.

So please let us know what you are meaning with stacking.

regards Holger

PS. Jim (M0CKE), congrats to find out the problems. Have you reinstalled all the other antennas again? tnx for calling me in the CQWW.

2187. Basic info please!!

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-11-01 20:20:22 UTC
From: kev haworth
Topic: 2187 Message: 2187

Hi!!
Just come across the hexbeam on a web page by John Tait
http://ireland.iol.ie/~bravo/ and am intrigued to find out more and
maybe home brew a mono bander...

I live right on the edge of a beach, and therefore have excellent take
off and a great salt plain for earth.

My problem being is my QTH is very small, a middle terrace 3 bedroom 2
storey house, with one big advantage, antenna friendly neighbours!!
the lot is only 20 metres front to back, so big towers are a little
prohibitive, but my neighbour lets me use his chimney to site a
rotatable 3 band dipole, which has been fantastic, however, I'd like
the edge a monobander would give me....

Would the group be kind enough please to advise me on some sizes/specs
to construct a mono band antenna for 20 metres please, as 20 is my
favoured band, and i'm nearing DXCC after just one years operating.

Best Wishes, and thanks in anticipation

Kev Haworth

Hi Holger

Nice to work you in CQWW, I was just playing and spent a total of about 10hrs operating over the weekend, was very busy!

Yes I have put back on antenna's to the point that it is the same as the Photo, I still need to try putting back on my Microwave beams which could be this weekend.

I have ordered some Amidon FB-77-1024 ferrite beads and some FB-77-5621 (for smaller coax should I require sometime) but the 77 material is discontinued in the 5621 instead they are supplying 31 material.

I had a shock with the cost of carriage though, the parts were $25 and the carriage was $23 .. total of $48.50 then I will have to pay import duty and VAT, I can see now why no one stocks this stuff in the UK .... it's a shame our economy is killing this sort of thing!

I'm hoping that when I install the Ferrite Bead Choke this will help the VSWR on 10M ..

Holger could you explain the Reflector element length affect on the antenna, Also the % Difference between Driven & Reflector affect on antenna and the Tip Spacing effects on antenna.

Thanks.

I hope to see you on 40m soon for a longer chat about the antenna.

Regards,

Jim M0CKE

2190. Comparisons

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-11-02 11:14:09 UTC
From: Darren G0TSM
Topic: 2190 Message: 2190

Hi All,
I've been carrying out lots of comparisons between my home brew 5 band hex and various other antennas. I thought the group might be interested in the results.
I tried this using two different radios, an FT1000MP and an IC756pro2. However between S6 and S9 the MP appears to be about 1.5dB per S unit where as my 756pro2 is exactly 2.5dB per S unit from S1-9 so I used the 756 for the S meter readings.
The Hex is a 5 band version using insulated wire mounted with the 15M element @6.5M. This was compared to a rotary 10/15/20m dipole also at 6.5M high. The antenna separation was 30M. The SWR on all 5 bands is below 1.5:1

10M Hex is 1 S unit up on dipole on front and 1 S unit down on the back side. So you could say it has roughly 2.5dB gain with 5dB F/B.
The Hex is also 1.5 S units down on a 3 element 10m monobander placed at the same height so it confirms the hex's gain theory i suppose. I tried to mount the monobander under the Hex but it screwed up the swr on all the other bands except when it was mounted at 90deg but I'll leave that as another project.

15M Hex is 1 S unit up on dipole on front and same signal on back, so needs some tweaking here.

20M Hex is 2 S units up on dipole (suppose due to losses in trap on dipole) and signals are 5-6 S units down on back.

12/17M were compared to a Windom @ 40ft and 90% of the time the Hex was better than the Windom and often the Hex was hearing stuff that was unreadable on the Windom. On 17 and 12M there are lots of big lobes and deeps nulls on the Windom.
When trying F/B to a local station 17M seemed about 5-6 S units down on the back where as 12M was about 2 down.

I had a good chance to play with the Hex during CQWW and compared it to a CB vertical mounted on a 6M mast and also a 15M sloping dipole with the highest point @12M high. The signals were about the same with the exception that the Hex was 2 S units up to North America on both 10 and 15M.

The biggest surprise was on 20M, usually I use the Windom as my 20M antenna and I was amazed to find that a VK6 was barely readable on the Windom but was 9+5 on the Hex. The same went for KH7X, no doubt again due to the lobes and nulls on the Windom.

You can draw your own conclusions from these non scientific tests, but I am sure my Hex could be optimised better. From my point of view to have an antenna where the wingspan is less than 60% than that of a dipole and still have some gain over it cannot be a bad thing.

Darren G0TSM

2191. Re: [hex-beam] Digest Number 611

Yahoo group: hex-beam (2001 — 2006)

From: tony dicenzo
Topic: 2191 Message: 2191

Thanks for the encouraging replys. To clarify what I intend to do, I have two Hex Beams, a 20m mono, and a 10-15. I intend to place them on top of each other on a mast and feed them with separate coax.

The mast will be on top of a flat room, appropriately guyed with steel cable.

They will be turned with a rotator mounted below the beams.

Mast will probably be 20' above the room max because of city code.

73,
Tony KX1G

Topic: 2190 Message: 2192

Darren,

Tnx for sharing your results. I find that your 1000MP S-meter seems to be off. I have measured the calibration of two MPs and both were essentially the same. The scale is in 1/2 S-unit increments. Using lab test gear, the S-unit scale was correct (6 dB per S-unit) from about S-3 to 20/9. Above and below that, the value changed a bit. I have no experience with the PROII. I also note that the FT-8447 has perhaps the worst S-meter in the world!

2193. Comparisions(Any diference between a rotary dipole and HExbeam 5i??

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-11-03 00:58:26 UTC
From: ct2itz
Topic: 2193 Message: 2193

Hi Darren,
I have order a HEXbeam 5i, and havent received yet, may be tomorrow
it will be here.

One thing i am sure , i have a rotary dipole with 2 traps
on both sides,(12..17..40), it have cost me only 200 USD with
shipping and the performance is excelent (also on 10 and 20 meters)...
I worked with it on CQ WW SSB and reports were always good (Low
Power).
Can someone explain to me: is there any REAL DIFERENCE BETWEEN
PERFORMANCE (REAL)OF A 1000 USD ANTENNA AND A 200???

Darren thank you for your studies..and keep giving us your
conclusions...
Thanks
Paulo

Hi Paulo,

I really don't understand why you keep asking the same basic question over and over. (He has asked off the list too.) Now that you will have the antenna for evaluation yourself very soon, you can make your own mind up on the performance difference. However, if you report that your rotary dipole performs as well as the Hex-Beam, then ... well I just don't believe you will.

When you assemble the antenna, pay close attention to the details in the instructions. Run the coax as shown. Put the ferrite beads on the coax as has been explained to you previously. Remember that they should be located just below the base of the Hex-Beam.

As one old song says, "Don't Worry, Be Happy!" My guess is that you will be thrilled at the improvement you experience Paulo!

I got good reports too, 1009 stations gave me 5/9 and 1 station gave me 5/7 ;-)

Hi Darren,

Have you tried to improve the f/b yet or are you still planning it?

I'm seeing between 3 and 4 lights (about 2S points) on my TS870 f/b but without actually knowing what one light on the 870 is it makes it difficult to know, Also every time I try to experiment the bands are full of QSB which is not much use!

I may need to set up a Sked with a few of you guys in the US to do some f/b tests .. Anyone interested?

Thanks

Hi Jim.
I'd really welcome that.. got the main idea of the hex now,
tried engineering composites in Chester for figreglass arms, but they
did seem extremely expensive and only sold in 5 metre lengths, which
would be wasteful..

Any info is greatly appreciated

Kev

Try Sandpiper
http://www.sandpiperaerials.co.uk
1/2" tube is £3.00 per meter. I bought some 1/2" and some 3/4" but the 3/4" isn't flexible enough. The 1/2" seems to be about right to use in one complete length. Actually I used black plastic conduit for my spreaders but they started to bend so I pushed the 1/2" GRP tube down inside the conduit, basically because I'm lazy and didn't want to strip the antenna down.

Hi Barry W4WB

Thank you very much for your concen mounting the antena.
Before buying the Heaxbeam i have search and gatter all fotos and
info i could: i have a Dossier from my dream antenna: the Hexbeam,
This information is mostly from you HEXHAMS in this site and others.
I was so impressed so i bought it: that´s i payed ..here in
Portugal
around 1400 USD for the HEX(antenna, shipping, VAT, Custom Taxes
and,,and,,,)never endind story.You are lucky to live in the
States...
I had very high expectations from this nice antenna ...lets see the
results..
Well one question: is there a special ferrite beads so i can order
today from Palomar Engineers may be.?? Here in Portugal nothing
available...
I am sorry may be my english was not good enough to understand the
study of Darren comparing to rotary dipole.
Tks a lot.....

Hi Paulo,

Nice term ... "HEXfun". I like that one.

On the home page of this site, I put information (in red) about the ferrite beads. You can order from Amidon. Please see http://www.amidoncorp.com/aai_productselection.htm and then click on Ferrite Shielding Larger Beads.
You want the FB-77-1024 (not the -1020). Presently, they are USD2 each. I suggest that you order at least 6 for the antenna feedline. I use this bead for other purposes too and so may you. Since the shipping cost is significant, you might consider ordering some extras. You DO NOT want the Type 43 material for this application. Oddly, some companies sell the Type 43 for this application or sell in-line baluns using it as well. I only note that the Type 43 has been readily available on the surplus market at a very low price.

HI Jim,

I can typically get on from about 2000-2300Z if you would like a sked during this time slot.

Also, have you tried using the NCDXF Beacons? They are a nice resource when testing your antenna.

Hi Barry,
I have ordered and received 12 FB-77-1024, and I plan on getting my hexbeam moved from my 30 foot tower to a new Aluma crank-up 40 footer this weekend. I see in your post below you recommend at least 6 beads. That is what I plan on using initially. I appreciate your comments about where to mount the "choke" in relationship to the plate. You mentioned you also use these beads for other applications. I assume it is for rf suppression, but can you give us some examples of other applications?
Thanks,
Terry, WK0F

Cheers Darren,
Rang san piper and they have some 4 metre fishing rod
blanks at 4.95 each... sound ideal, also the tip can be removed, and
apparently, is the perfect size for a 2m delta loop...waste not want not.

Been to B&Q today and bought a pack of 10 8 foot bamboo canes for
2.95... looks like these are going to be my prototype, and 15 metres
now looks favourite

Kev

I'm working 40W into a mismatched vertical and I had to work for over a minute with a couple of guys to get my callsign through.

Everyone gave me a 59. (Contests aren't the time to get accurate signal reports.)

My fishing pole experiment literally exploded. They were crappie poles and most of the flex was in the last 1/3 of the pole. I removed the tip as well. There was no way it was going to meet the 10-15m elements on its way up to the 20m element. So if the poles are very big at the butt end (these were > 1") you might not have any luck. I had the same poles the moxon project uses for spreaders, which I see why they worked good for that since they are fairly stiff.

I did what I should have to begin with and bought fiberglass from max gain. I'll report my hopefully successful config soon.

Hi Kev

For fishing rods take a look at http://www.jims.org.uk/fishing/poles.htm I
used the 1056-400 take out the tip and just use the first 3 sections ideal
for the 5 bander, £2.99 each ...!

Most of my other parts came from CPC .. will send a list soon as I have time

Jim

2207. Re: Use of ferrite beads

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-11-03 19:34:58 UTC
From: w4wb
Topic: 2199 Message: 2207

Hi Terry,

Tnx for ur comments. I do use the beads for RFI suppresion of RFI generated by the motor in the various motorized mobile antennas I have. I make 3 loops through a bead and it is quiet (effect of 9 beads). Although not this bead, but the same material, I use it in the speech compressor we make at W4RT Electronics for HF operation. We "team" the bead with a Type 43 bead to handle RFI issues in the VHF and UFH bands. Type 43 is good for VHF and UHF while Type 77 isn't.

73,
Barry W4WB

2210. RE: [hex-beam] can hex beams be stacked?

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-11-06 14:36:59 UTC
From: Mr David Jordan
Topic: 2183 Message: 2210

Yes they can. Heres how
Assuming vertical stack.
Pick a distance 30 to 40 feet apart.
Run equal lenghts of 50 ohm coax to each hex beam.
make sure you keep the feed polarity correct.
You can feed it thru a stackmatch or make your own.
you will need to make a 50:22 ohm transformer out of a
ft-240 #43 core. Look in antenna hndbook on info to
make this transformer. It consist of about 5 trifilar
turns of #14 wire on the core.
Now get 3 spdt relays. for high power use 10A type
12V
The input is default switched to the 50 omh port of
the transformer. The other 2 relays commons are
conected to the 22 ohm port of the transformer. the
NC positions are connected to the 2 antennas.
Depending how you, wire this you can have transformer
in our out. ant 1, ant2, or ant1&2.

If you are stacking inb the horizontal plan do the
same thing but keep spacing 30 feet

2212. More Basic Info Please

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-11-08 22:40:43 UTC
From: gerry_schjelderup
Topic: 2212 Message: 2212

After one false start, I am assembling a 5 band hex beam according to the specs of DL7IO. Although the procedures should apply to all models, what is standard practice when one begins to adjust element lengths on the driven, what is done regarding the corresponding reflector?
Gerry KC0MSX

From: Jim Balls
Topic: 2212 Message: 2213

Hi Gerry,

I've been trimming my hex for the last few weekends, I have not cut off the excess wire for a start I have just folded the wire back (Un-insulated) and tied the tail / element together with ties / tape.

I started by shortening the driven elements, (20M first) some by as much as 15cms each, but then I noticed the F/B had gone, so then I shortened the reflector to 3% longer than the driven, this then gave me the f/b but i noticed the elements were then resonant further up the band, so I lengthened each by the % calculated to shift them by the amount required and that worked.

I'm seeing about 12db F/B with a local station on 20/15/10 and about 18db f/b on 17/12

I'm no expert and this has been a big learning curve for me, I've found the spreadsheet invaluable in the calculations of the element lengths, trimming length calculations and to get the Reflector 3% longer than the driven.

Trial and error, every time I changed something I put the antenna back to 25' to test it.

Not sure what wire you are using etc

So start with 20M work down but be careful as each band effects others so get each band close then move to the next one, final small trimming at the end to get the desired results.

I hope the above is helpful and can be backed up by other home brewers.

Regards,

Jim M0CKE

2214. Re: More Basic Info Please

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-11-09 09:08:08 UTC
From: gerry_schjelderup
Topic: 2212 Message: 2214

Hi Jim,
Thanks for the note. I started out using insulated wire and surmised that the 20 m band would require a 15 cm reduction. I then determined a shortening ratio, (I think it was something like .9725) and calculated a similar shortening to the other bands, and on the reflector elements also. I also used the same shortening ratio and applied that to the tip space. Although I only got to cutting and mounting the 20 meter element, I gave up on the insulated wire approach because there were to many things I was unsure were correct. I had also planned on doing only 3 bands, 20, 17, and 10, as it seemed that the fishing pole spreaders were too stiff near the hub and seemed to leave the higher band elements too close together. The wire I am using now is copper coated steel and I have only mounted the 20 m element so far. It seems that thinness of the spreader tips are having some difficulty in keeping the elements sufficiently taut. Don't know yet how I will resolve that--or live with it.
I must admit this hex project does pose some difficulties, but it has been fun and should prove to be a learning experience. I know the hex beam has real merit as I am pleased with 10 meter one that I have had up for several months. Thanks again for the note. 73

From: worsr
Topic: 2216 Message: 2216

I have just put up a 6M hex. The SWR seems high to me. The best I can get is 1.7:1 at the bottom end of the band. above 52.5 MHz, it is about 2.5:1. Antenna is about 22 feet up not near anything metal. Swapping coax didn't help. Does anyone have any experience with this antenna that could lend expertise?

Thanks!

Mike, W0RSR

I used 1" PVC conduit for the spreaders. After a while the whole antenna started to sag down with the 10M element ending up about 4" below it's feed point. I pushed 1/2" GRP tube into the conduit to reshape it.

From: David Douglass
Topic: 2218 Message: 2218

Hi All,

I'm starting to assemble the bits and pieces for my 3rd 5-Band Homebrew HexBeam.

Unlike the previous 2, I'd planned to make this a little more robust and was thinking about installing the feeder inside the centre post, as oppossed to running down the front of the PVC pipe. By feeder, I mean the twin line between the elements and not the actual coax.

Has anyone succesfully achived this ?? and if anyone has some tips or photo's of how they managed it, I'd ;ove to hear from you.

Like my previous 2 Hex Antennas, I will be using 16mm Tasmania Oak Dowling for spreaders, but this time around they will have a outer PVC sleeve, for extra strength and durability. I've even gone to the expense or ordering some real 14AWG antenna wire from the US for this one, as opposed to using speaker wire.

Regards All

David, VK2NU (ex VK2DPD)

Dennis,
I used 1/2" pvc pipe to do a 10 meter beam that has worked out
fine however it has only been up for 3-4 months. A larger antenna
would warrant using thicker pvc, however, in any case, it would be
wise to give it a good coat of paint to prevent deterioration from
the sun.

Does anyone on the SIG have experience with the 6M monoband Hex? I put one up, but SWR seems higher than I would like. The lowest I can get is 1.7:1 at the lower end of 6M. Above 52.5 it is above 2.7:1. Antenna is not near any metal objects and is about 23 feet up in the air. I've tried different coax with same results.

Thanks for any ideas.

Hello David,
except of the test/prototype versions all my homemade beams came with the feeding inside the center post.
This will take you some time and passion!
I'm doing it the following way:
The holes in the center post have to be drilled.
For connecting I'm using screws from brass because they can be ironed to the wire of the low impedance line. The wire I use for the feeding line is insulated. I cut of about 1 cm of the pvc at the points where I connect the wire elements and iron the brass screw to the devided flexible copper. Remember that you need a few millimeter more feeding line than distance between the holes!
Once you have prepared the two lines put the screws from outside into the holes and fix the feeding line together with cable strips or tape but so, that the wires are as close together as possible except where the screws are.
For the screws length you should check the inner diameter of the center post. My center posts are from fiberglas (the same as my spreaders) and have 34mm inner diameter. I use screws with 16-20mm length from brass.
Before inserting the feeding line connect your coax cable as well.

Than put the construction inside the tube and use the holes for the reflecter connection with a small screwdriver to get the screws with the feeding line into their holes. Once you got a screws in the hole put a nut on it but not strong to be able to move the wire a bit. If both screws are in place you can tighten the screws using spring washers.

For the reflector side I made a "special tool" out of a 3mm thick copper element. At one end I have bended it like a clamp to hold a screw. This is used to get the reflector screws into position.

For connecting the wire I have made special nuts from brass very similiar to those Traffie is using. I still have a few thousend left if you like. They are seen on the "parts" site.
www.dl7io.de/reflectedw_parts.html
Before I had those the wire often did break because it was bended here.

I have made a 5 band feeding system last week for a friend. This is ready but this weekend I will do one for a 40 m version. I can make a few fotos from this process if you like.

regards Holger

Hi Art,

Purpose is to mitigate any common-mode current that may be present upon the outside of the coax shield, thereby keeping it from radiating. A simple test to see if you have the problem is to take a section of coax several meters long. Pick a freq and measure the SWR with your present feed line. Now insert the extra coax between your present coax and the SWR meter (making the feed line longer). Measure the SWR again. If it isn't the same value, then you have a common-mode current. See Walt's book entitled "Reflections II" for a more complete discussion. When you eliminate the common-mode current, the SWR is the same value independent of where you measure along the feed line.

Hi Paulo,

I looked at the Wimo site, but not sure which balun you are buying. It should be 1:1 and use Type 73, 77 or F materials. I use the DX Engineering balun (http://www.dxengineering.com/pdf/P-Balun.pdf) with my GAP Titan vertical antenna. Works fine.

Locate this balun just under the hub (or base plate) of the Hex-Beam. You do not need the beads or should you attempt to use a coax choke. In other words, just use the Wimo balun.

The Type 77 beads work far better than the coax RF choke.

Keeps us posted on your progress.

73,
Barry W4WB

2229. To Barry and friends : 6 Amidon FB-77-1024 beads V Dx Eng Balun; Which the best?

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-11-16 00:10:22 UTC
From: ct2itz
Topic: 2229 Message: 2229

A commonly asked question is what material should be used for an RF choke. For the HF bands, the best material to use is Type 77 (or 73) ferrite beads. About 6 Amidon FB-77-1024 beads side over RG-213 and can be held in place with heat shrink. (Do not attempt to glue the beads together.) This balun should be located just below the base of the Hex-Beam, never within the elements or above it. Type 43 material is not appropriate for HF, but is the material of choice for VHF and UHF. A coax balun is an alternative, but suffers less attenutation and poorer bandwidth.

This is what we have in our home page can anybody help in this real confision??????
Thanks vert much
Paulo

PS I would like very much MR. Mike to gove his opinion, is it possible for you to writr some words to your customers regading this subject???
I will wait...never had a help from you even when requested..i am sorry but i had to say this. We pay very expensive for this small antenna...nevertheless The construction company is not active and help , why???
I want to thank to W6HB, Dough; Barry, other colleges that had really very helpfull, much more than the Constructer..What is wrong with this servive after sale, why you do not hel the customes, every tine i needd to make a call that is 30 USD,why, why, why ?????

2230. Rotary Dipole

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-11-15 19:42:44 UTC
From: Stuart Bloom
Topic: 2230 Message: 2230

Hi,
My primary beam antenna is a Cushcraft A3S tri-beam Yagi. It was designed with 3 elements for 10 -15-20 meters. I added the "40 meter stinger kit". This adds additional traps and capacitance hats on the driven element only of the tri-beam. 10, 15, and 20 meters are largely unaffected. What you get is a trapped 40 meter "rotary dipole" up at 50 feet (where my antenna is).

I have direct comparison experience with a 40m dipole at 33 feet. The 40m element on the tri-beam works noticeably better than my dipole. You don't get any front-back gain (since there is no director or reflector for 40m), but you do get some dipole end-fire versus broad-side gain when you rotate the beam for optimum beam pattern and reception. I guess the height / directivity gain outweighs the loss from the traps. I'm happy with it.

I guess a 40m Hex would be really really large. Has anyone built one?

I'm still working on my first hex. Maybe this winter. Our club uses one for field day / emergencies.

Paulo,

What is it that you don't understand about the ferrite beads info I put upon the home page and you cited below?

Mike Traffie has talked to you on the phone and answered many questions you have asked. I know this because he told me so.

Mike does NOT have any email capability and he does NOT monitor this or any other web site. In other words, call him or send him a FAX. Remember, there is a big difference between customer service and "hand holding". If you want hand holding, you should be prepared to pay for it, and not just as telephone charges.

I am glad that several of us have been of help to you Paulo, but you keep asking the same questions over and over, and they have been answered to the extent practicable. I suggest that you just assemble the antenna, attach the coax with the balun, get it up in the air, and enjoy using it. It is easy to assemble, with the help of two friends, in 2-3 hours the first time. One friend and I can put one up or take it down in about an hour since we have some experience. If you have some issues after it is up and tested, then perhaps we can help more, but I expect it will be just fine.

Good luck es 73,
Barry W4WB

2233. Re: Rotary Dipole

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-11-16 14:45:31 UTC
From: dl7io
Topic: 2230 Message: 2233

Hello Stuart,
I have built 4 different designs starting from a 40m monobander via 40/30m, 40/30/20m to 40/30/20/17m which is currently in use.
Details and EZNEC simulation of the designs can be found on my webpage.
The diameter is 12m. The reflector of the A3S is about 11m. So for a 40m beam it is small. The weight of my mechanically redesigned 40m version is about 17kg now (bigger sized base plate).
We are currently discussing a 80m version for our contest station.
This will have 24m diameter and I would design it for 80/40/30m
regards Holger

Topic: 2235 Message: 2235

Mr. Barry, let me tell you some words that might be useful;
1) i were not born with all our capacities , speacillay to bild this Antenna;
2) Customer satisfaction programe??: Call TGM in Canada..and speak to the owner and see how friendly he is..; Call In Germany the manufacturer of Spiderbeam. he answer back in moments....call Optibeam and see MR. Thomas giving 100 Customer Service... Why not in Hexbeam??

3)When i bought the antenna MR. Mike told me that the best shock was several turns of coax in a bottle of softdrink..so we do use the same info...and when i buy a 2 element beam for mores than 1200 USD i expect some help from the person who sold me...or not???

4)I really do not understand why you keep picking om me with hard words,,the only thing i did was asking a question that is not accuratted.
Sorry to disturb you..remenber we are always learning in life, and with this kind of answers ...really do not feel welcome..or understood.

I am a teacher and my previlege is to teach the students who are intrested in learninhg...

Well MR. BARRY iam but i do not ever LOOSE PATIENT WITH THE ONES WHO SEEK FOR MY HELP.

I have to appologize for the rest of us here in the states for your being offended. I really think that Barry did not intend to be critical of you.

I know that there is a bit of a language communication problem. Probably Barry would be kind enough to further answer your questions if you asked them to Barry in Spanish or Portugese (I'm sure he's fluent in these languages) that way he could reply directly to you in your choice of languages. This way the detail of your questions would not be lost in the translation. Also that way you could get clear and concise answers to your questions.

I am sure you will be happy with the hexbeam once you get it up and start using it. Its a superb antenna. Also, you are correct about the cost of international telephone calls. The cost of them doesn't bother the aerospace types here in the states but it is quite expensive for us average guys.

Incidentally Barry, here is my direct email address if you wish to comment to me directly. kd6wd@...

Paulo, Olla, I believe I see what some of the problem is that you are having. I do not speak Portugese but I believe your are having some language problems both on your side and us on this side. Might I suggest that you have a fellow amateur who has a better command of the English language post your question and also do the talking to Mr. Mike so that he may tell you what your looking for in your language so that it is understood.

Many of us that speak English as our native tongue forget that English is the hardest language in the world for people who don't speak it. Being a school teacher I'm sure you probably speak 3 or 4 languages fluently but not English.

So please bear with some of us and maybe these ideas will help you.

Ciao, 73
Mike

2238. English Language Problems!! (May be???)

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-11-18 00:30:41 UTC
From: ct2itz
Topic: 2238 Message: 2238

Good evenenig to all fell Radio Hams on this excelent Forum.
I do not want to go on with this speech, because i see you do not understand the issue.: There are different information regardinfg the same issue, like the one with Shock..!! What could be a solution, the Constructor could give us a help..
Well every teime i have a problem assembling the antenna i have to make a phone call (intercontinental) that costs me between 30-50 USD depends on the time spent on the home. I could send an e mail..but Traffie Company does not have one..so..please tell me what to do..I reaaly have to thank all the Radio hams that have been so nice to me and had the patient to answer my questions, really THANK YOU, but unfortunely can not say the same about the Constructer.
The antenna is already expensive...more international phone calls.....is this an never ending story..fortunely this Forum exist.
By the way my HEXbeam is registred with Serial number #349
I am sorry having to bring this subject here..but felt really unfair having to spent $$$$ in calls to have assistance, something i am entitle for free....no follow up.....so i think my problem is not the english language...
Take Care and God Bless to you all

Dear Paulo,

I was also a teacher (an university professor in EE) for many years and I agree fully that it is a privilege to teach students who are interested in learning. Problem becomes when the student does not learn and the teacher's patience has been exhausted.

Some of us who have tried to help you are now thinking "If Paulo did not want my answer, then why did Paulo ask me the question?" [For those on the hex-beam list, you should understand that there have been a number of direct emails attempting to help Paulo.]

In the spirit of trying to help you understand the RF choke matter, I will attempt to explain it one more time.

1. There are a variety of ways to suppress the common-mode current. Reading Walt's (W2DU) book entitled "Reflections II" can add greatly to ones understanding. This current is often the source of RFI problems as well as others.

2. You have to select a method and implement it. Don't implement more than one method unless you really understand why you are doing it.

3. The different methods generally do not provide the same performance.

4. The different methods require varying amount of work to implement as well as cost.

5. Example methods. Balun should be located as close to the base of the antenna as practicable.

5.1 No balun, but you adjust the coax length to get the SWR to an acceptable level. This method is rarely used anymore and isn't recommended.

5.2 Coax balun: This comes in two types, one being scrambled wound and the other as layered. Layered is preferred. Only cost is the coax and whatever coil form you use. Performance (frequency range covered and attenuation) is determined by coax type, coil diameter, and number of turns. It is not as easy as one might think to "get it right" making this type balun. See the files area for a document on this subject that contains some useful guidance. [Files -> Publications -> airbalun.html] Many people suggest using the rather common coax RF choke, as Traffie mentioned to you, because it will work to some level. A little coax and a piece of PCV as the form

makes it easy enough to build, if you get the number of turns and diameter correct. FWIW, I understand Traffie will be soon stocking the Type 77 beads to make it easier for customers to acquire them. However, for those of us living in NA, it is easy to get the beads from Amidon ... just call 800-898-1883, and they accept small orders and your credit card. For folks not in NA, it can be more difficult so it is common to suggest the coax balun. I certainly have for people in really remote places where just having coax is a treat. Recall please Paulo that you stated your concern for suppressing RFI and wanted the most certainty you can have that you will be successful. This concern is why we have repeatedly urged you to use the ferrite beads instead of the coax.

5.3 Commercial baluns: These are pre-built by various companies and vary in performance. I rather like those from DX Engineering. The W2DU type balun is offered by the Wireman (uses Type 73 ferrite beads which is fine). There are some companies that offer HF baluns made using Type 43 material. As I have explained before, Type 43 is inferior to Type 73 or 77. In any case, I would avoid Type 31 because of its low Currie temperature.

5.4 Ferrite beads: See the home page for details. In short, slip about 6 Type 77 (Amidon FB-77-1024) beads over the coax, cover with heat shrink, and the problem should be solved. I suggest the use of fully shielded coax in general; however, if you want to add a lot of beads (logic being "if a few are good, then a lot must be better"), then you can actually cause power loss by shield leakage if you are using partially shielded coax.

I understand you have purchased a balun from Volkmar's Wimo company in Germany and it will likely be fine. I have not tested the one he sales, so no endorsement or criticism from me. However, Volkmar is very serious about selling good products and I again suggest that it will work fine.

Now is the time, I suggest, to stop the gedankenexperiement and just get the antenna erected, and then let us know how it works! If you experience specific problems, then please provide the group the specific details and I expect you will receive some useful suggestions.

GL es 73,
Barry W4WB

Hello Paulo,

I am most pleased that you believe that the English language isn't the problem; however, I am not so confident language isn't a part of the problem. From what I understand from your current message, you are having trouble assembling the Hex-Beam. Is it possible for you to explain exactly what problems you are having. You may write in Portuguese if that will be easier to make your questions clearer. I am not fluent in Portuguese, but I have a ham friend that is very fluent in Portuguese. In this way, perhaps you can receive the help you need.

Assembly of the Hex-Beam is straightforward and the instructions are clear (to me at least). You do need at least one person to help you and it helps to mount the base plate upon a pipe that will hold the base plate about 1/2 meter above the ground.

Regarding your complaints about Traffie, I have never heard of anyone else saying that Mike wasn't willing to talk to them to resolve their questions for as long as needed. Have you sought help to do the general assembly of the antenna from other hams in your area since there are over 4,000 hams in Portugal.

73,
Barry W4WB

Hi Paulo,
Don't know for sure if this is what you are looking for;
2 X-FP-77-1024 Euro 4,98

Ferrit-Materialien zur Funkentstörung
Im Folgenden ist eine Liste der größeren Ferritperlen sowie Ferritringkerne aufgeführt, die für Entstörprobleme häufig benutzt werden. Die größeren Ferritperlen und Ferritringkerne können zum Abblocken von HF auf der Abschirmung von Koax- und Mikrofonkabeln sowie unabgeschirmten Kabeln wie Lautsprecherleitungen und Netzkabeln verwendet werden.
In vielen Fällen wird eine einzige Windung durch den Kern eine ausreichende Dämpfung der unerwünschten HF bewirken. In anderen Fällen werden vielleicht mehrere Windungen notwendig sein, z.B. bei Netzkabeln.
Außendurchmesser: 25,40 mm (Outside diameter)
Loch: 12,70 mm (Inside diameter)
Länge: 21,00 mm (Length)
Typische Impedanz bei
25 MHz: 166 Ohm
100 MHz: 135 Ohm

Go to www.amidon.de. It is all in german language and more expensive than in the USA.

Webshop; http://www.amidon.de/websho/stratoindex.html

Look under Amidon-Entstörmaterial
Regards.

Subject: [hex-beam] To Barry and friends : 6 Amidon FB-77-1024 beads V Dx Eng Balun; Which the best?

A commonly asked question is what material should be used for an RF choke. For the HF bands, the best material to use is Type 77 (or 73) ferrite beads. About 6 Amidon FB-77-1024 beads side over RG-213 and can be held in place with heat shrink. (Do not attempt to glue the beads together.) This balun should be located just below the base of the Hex-Beam, never within the elements or above it. Type 43 material is not appropriate for HF, but is the material of choice for VHF and UHF. A coax balun is an alternative, but suffers less attenutation and poorer bandwidth.

This is what we have in our home page can anybody help in this real confision??????
Thanks vert much
Paulo

PS I would like very much MR. Mike to gove his opinion, is it possible for you to writr some words to your customers regading this subject???
I will wait...never had a help from you even when requested..i am sorry but i had to say this. We pay very expensive for this small antenna...nevertheless The construction company is not active and help , why???
I want to thank to W6HB, Dough; Barry, other colleges that had really very helpfull, much more than the Constructer..What is wrong with this servive after sale, why you do not hel the customes, every tine i needd to make a call that is 30 USD,why, why, why ?????

Hi Wayne,

Welcome. Yes, it does have a from and back. The reflector is a bit longer than the driven element, but both are in the same structure. Look on the home page of this site and see the upper left photo. I highlighted the element in color to make it clearer which is which, and the beam heading. Does it work? You bet. I have almost 300 entities confirmed using it and Tony AD1Y (right-side photo) has all but a couple of entities now. Ed 4L4FN (gentleman that is best known for his operation in P5-land and now is in D2-land) found the 10-15 m Hex-Beam to work great when he was in North Korea and now he has the 5-band version in Angola. I am having another one made by Traffie that covers 30 and 40 m. :-))) Does it hold up in bad WX? Yep. Mine has seen modest 60-70 mph winds. W2GFF near Mobile, AL had no damage to his when hit by > 100 mph during the huricane this summer. Stands both heat and cold well.

Hope this helps.

There are reasons why he hasn't had email. The mater is being worked on, but not sure if it will be resolved. He has an 888 number, so just call him. He is generally able to talk when one calls, but if not then, leave a time span he can return your call.

Hi Barry,
Thank you for your help and comments. I took a look at the picture in your Word document. Thanks. Are you the group moderator or just an enthusiastic Hex Beam owner?
I notice in the discussion of RF chokes mention of using a type 77 ferrite beads. Do these come in different diameters? RG-213 is a smaller diameter than the RG-8X that I'm currently using. I have been away from things long enough to ask a really bone head question: shrink tubing- can it be shrunk using a hair dryer. Are you using the HDX mast from Traffie? I'm curious how much it weighs? If you get too much weight I wonder about fitting the whole thing into the hole (never mind about play on words). In Traffie's documentation for the push-up mast, he shows a ground mounted rotor, how is the rotor kept from rotating? I ask all this with the knowledge that there is no truly dumb question more than the one not asked. I guess? What type of guy wire do you use? Is expensive Phillystran necessary? How about Dacron or polypropelene rope? I was going to send this as private mail but I don't mind coming off as a novice. I am in some areas, not in others, so I'm also sending to the list.

No question is stupid - they all sound good questions to me. As for heatshrink tubing - I ended up buying a heatshrink gun. I am not sure if a hairdryer will be hot enough. My immediate answer is no. At a push we used to use a soldering iron held near the heatshrink. It works if you are careful but still doesn't beat the result with a real heatshrink gun. If you had an electric paintstripper - that might work with care. Again I bought my heatshrink gun in 1990 and am glad that I have every time that I deal with heatshrink tubing.

This seems like a good alternative, EXCEPT, if you already have the cable assembled. Believe it or not, not all hams are adept at making up cable connectors. At least my memory recalls poor attempts.
This is a kit suitable for RG-8 diameter cable for $15, I wish the beads were split. Any thoughts? Anyone?

This is from the antennex balun kit page, they think a lighter is sufficent:
"

Baluns are used to connect balanced antennas to unbalanced transmission lines (coaxial cable). They prevent antenna currents from flowing down the outside of the cable. They should be located right at the antenna. They can also be used as "line isolators" anywhere along the cable to prevent flow of induced RF.

These balun kits are 1:1 current baluns. They consist of five large ferrite beads (total length 5-1/2 inches) that slip over the coax. Also included are three lengths of shrink tubing to enclose the balun and hold it in place on the cable. The baluns are for use from 3.5-60 MHz and allow use of RF power to the full capability of the cable. No tools are required for installation, just a source of heat to shrink the tubing. Heat gun, lighter, matches."

Hi Wayne,

Comments are embedded below.

--- In hex-beam@yahoogroups.com, Wayne Busby <wa6fxl@e...> wrote:
> Hi Barry,
> Thank you for your help and comments. I took a look at the picture
in
> your Word document. Thanks.

Are you the group moderator or just an enthusiastic Hex Beam owner?

Yes and yes.

> I notice in the discussion of RF chokes mention of using a type 77
ferrite beads. Do these come in different diameters?

Yes.

RG-213 is a smaller diameter than the RG-8X that I'm currently using.

Huh? 213 is 0.405" OD and 8X is 0.242" OD. For the 213 use the FB-
77-1024 (0.500" ID) or the FB-77-5621 (0.250" ID). I haven't given
the 8X issue any real thought, but first guess is to use perhaps 10
or so beads.

I have been away from things long enough to ask a really bone head
question: shrink tubing- can it be shrunk using a hair dryer.

My experience was that a hair dryer isn't adequate. Get a heat gun
or as an alternative one of those paint remover heat guns from places
like Sears.

Are you using the HDX mast from Traffie?

No.

I'm curious how much it weighs?

I don't have that information. Two people can erect it.

If you get too much weight I wonder about fitting the whole thing
into the hole (never mind about play on words). In Traffie's
documentation for the push-up mast, he shows a ground mounted rotor,
how is the rotor kept from rotating?

There are different way to implement the rotor. One key point is
that you have to have a transition piece made unless your rotor
accepts the diameter of the mast. As I recall, we sent Ed 4L4FN one

with the mast while he was in P5-land. Mounting the rotor depends upon the rotor. Some have a base plate to bolt down while others need to be attached to a pipe with clamps.

I ask all this with the knowledge that there is no truly dumb question more than the one not asked. I guess? What type of guy wire do you use? Is expensive Phillystran necessary? How about Dacron or polypropelene rope?

First, never use guy wire. I use Antenna Rope made by Synthetic Textiles of Anaheim, CA (714.630.2134), which is a double-braided Dacron/polyester material. It is black. My experience with it has been excellent ... no faults, frays, or stretching. I highly recommend using the single Butterfly knot (http://osaka70.site.ne.jp/e/rope/middle.html) to fabricate a "rope pulley" to properly and easily tension the guys.

I was going to send this as private mail but I don't mind coming off as a novice. I am in some areas, not in others, so I'm also sending to the list.

Wayne,

This is the same as the Palomar. They had been using Type 43 material. Maybe check and ask them if you like. Regarding the snap-on or split beads, one must be careful when using the snap-on type. Some can damage the coax over time due to their design. I don't know of split beads made of 77. As I mentioned before, 43 works, but far poorer than 77. You are making a significant investment in time and $$$, so why not select the better?

I suggest that you would be better off cutting the connector off of your coax, put on the beads (remember to keep the beads just below the antenna), and install a new coax connector. Maybe you have a friend to help if you feel uncomfortable installing the PL-259. I note that a common problem I see is with installations (home and mobile in particular) is that the coax connector was improperly installed. May I suggest Greg W8WWW web page on coax connector installation (nicely done IMO) ... http://www.seed-solutions.com/gregordy/Amateur%20Radio/Experimentation/SolderCoax.htm

None of us were adept at doing coax connectors. It only takes a few tries to get hang of it. You just need a box cutter , a pair of diagonal cutters, and a soldering iron with some solder. Just make sure you don't get the frayed braid pieces to short out the center conductor. Radio shack has a crimper if you prefer crimp style.

This seems like a good alternative, EXCEPT, if you already have the
cable assembled. Believe it or not, not all hams are adept at making
up cable connectors. At least my memory recalls poor attempts.
This is a kit suitable for RG-8 diameter cable for $15, I wish the
beads were split. Any thoughts? Anyone?

Good point Barry,
I agree on the reduced reliability of the crimp style especially if there is a strain on the cable, I usually use crimp types only indoors. Or on quicky field day type setups.

Good input

Hi Wayne,

No sir. RG-213 and RG-8 (Belden #8214) both have an OD of 0.405". RG-8X (also called Mini-8) has an OD of 0.242". These are also the ODs that work well with the PL-259.

2260. RE: [hex-beam] Amidon Ferrite Beads

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-11-20 23:47:37 UTC
From: Larry
Topic: 2249 Message: 2260

I got this from an article a little while ago. I think I got it off a QRP forum but they use 5 beads 1.125 in x .25 d.
Mouser # 623-2643540002

The problem is that some of the RG-8X is a little bigger than others and these beads are real tight, and on some 8X they won't slip on at all.

Mouser has some bigger beads but with a lesser value so I guess you could just add more beads.

I hope this helps.

Larry

2261. Sealing connections

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-11-21 02:12:46 UTC
From: w4wb
Topic: 2261 Message: 2261

One thing that hasn't been discussed recently is protection of the connectors.

Two simple and good things to do are as follows:

1. Use a compound like "PENETROX A" to accomplish a solid electrical connection between the metal parts of the connectors (as well as other such interfaces). Also helps to mitigate seizing. Good source is DX Engineering.

2. Seal joints and connectors with something like Coax-Seal to protect against water or other contaminants leaking into the connector. Available at most ham radio supply companies. WARNING: You can use RTV, but be certain it isn't the type that gives off acetic acid while curing (if it smells like vinegar, you got the wrong stuff). This can cause corrosion. DX Engineering sells some stuff that is okay and I have seen others. I find that Coax-Seal does the job for me.

These little things will keep your antenna maintenance down significantly and your performance up.

From: dl7io
Topic: 2262 Message: 2263

Hello George,
are you looking for measurements anybody has made on the antenna or asking for the dimensions of a 20m version?
I guess you are talking about dimensions. Check the article from Mike Traffie in the file section or check out the webpage of EI7BA. He describes a 17m homemade project and gives you some formula to calculate another band.
I have calculated a number of beams with EZNEC also single band versions from 10-80m The only single band I have built is 40m. Here the dimensions worked fine. My results can be found also in the file section under Dl7IO or on my webpage in an excel file called:
reflectedw-single-band-koordinaten.xls
best regards Holger
www.dl7io.de

PS: We will take part in the CQWWDX-CW next weekend as DL7IO in the Multi2 category. Among other antennas we use 2 hex's I built the last 2 weeks. One is a "40-4" for 40/30/20/17m and a "20-5" (20-10m). So please all of you give us a call. tks

Paulo,

Glad you received the beads. Take 6 of them and locate them on your coax just below the base of the Hex-Beam. Actual location isn't very important to within a foot or so; however, do not allow then above the base of the antenna. (Depending upon how you have things arranged, you may have a relief loop in your coax for your rotor.) Also, be sure to run your coax exactly as shown in the instructions ... down the COLD side of the center support between the reflector lelment and the driven element.

There are many ways to hold the beads in place. I cover then with heat shrink and hold in place on the coax with cable ties (being careful not to overtighten the cable ties (you can hurt the coax). Do not glue the beads together.

Paulo,

Doug and I have sent you direct messages. Perhaps they will help.
Your questions about email have already been answered. Perhaps you
should write out what you want to ask and send to Traffie by FAX.
That costs less than a phone call. He will respond I feel certain.

Please look at the messages in the hex-beam archive and you will see
that I have answered the below questions already. Take the time to
locate and read them carefully, and perhaps print them out.

Good luck,
Barry W4WB

Topic: 2271 Message: 2271

Hello,
I have calculated the wind load for my beams.
No1. 20-10m seen from top 0,488m²/5,253 ft² and from the side
0,178m²/1,87ft²
No2. 40-17m seen from top 0,976m²/10,5 ft² and from the side
0,607m²/6,38 ft²

my spreaders are 14/24mm or 0,55/0,95in (top/bottom) in diameter for
the 20m+ version and 16/29mm or 0,63/1,14in for 40m+.

regards Holger

2272. 5 band model

Darren,
Look in the files area (Folder called DL7IO I believe). Holger has made a number of models, including some multiband ones. I suggest you bear in mind that the model is "better" on receive than transmit due to the modeling method used by NEC.

Hello to all of you Hexbeam-builders-users etc.
I have upload all my pictures I made from the building of my Hexbeams in my photoalbum. Im busy to make my second Hexbeam from glasfibre fishingpoles and like to share these pics with you. In the feature I will edit all the names of the photos.
You can see them to click on my Yahoo-icon and you see my profile. At the left of the screen you see the link to my photoalbum with all the Hexbeam photomaps.

Hope you can use the photos to build your own Hexbeam, mine first one is working very fine and thats why I building a second one for /P use. Easy to build up and easy to brake down lol.

Best 73's de Jan PA2JJB

Hi Jan,

Nice job and good photos. Can you pse comment on the SWR plots you showed? Looks like some bands (10-15 m) are rather high (over 2:1).

Again, very interesting project and I look forward to your next version.

73,
Barry W4WB

2278. 6 M Hex Beam

Yahoo group: hex-beam (2001 — 2006)
Date: 2004-12-14 07:39:13 UTC
From: John Titterton
Topic: 2278 Message: 2278

Greetings from Cape Town.

I am busy constructing a 5 band Hex (10 - 20 m) and hope to have it completed in the next few weeks. However, whilst getting all the bits and bobs ready for the 5 bander, I am looking at also building a single bander for 6 metres and am wondering if anybody has the measurements for doing this. I have looked in the groups files folder on Yahoo and can find no info for 6 metres - maybe I am a bit blind and missed the info. Can anybody help or point me in the right direction.

Regards

John

Make your own figures with these numbers it will come very close to
computer model
N9IWW if you need them in meters do to DL7IO.DE web page he has them on
his web site.

The guys on the HEX reflector all agree the following...

Driven Element = 6180/Freq
Reflector = 6262/Freq
Tip Space (Driven Element) = 102/Freq

Tip Space (Reflector) = 65/Freq
Overall Tip Space = 145/Freq
Answers in inches...

John,
I have also built a 5 band Hex (10 to 20m) but will wait til Spring before I complete and install. But I discovered that the ends of my fishing poles not used on the 5 bander would be ideal to make a 6 meter Hex. Would like to make it a 'portable' and function like an umbrella. The problem I see there is the inflexibility of the elements. Any ideas-- or is this not practical?

Gerry,

I am not using fishing poles for my 5 band Hex. I am using 12mm solid fibreglass rods which I purchase in 6 metre lengths from a manufacturer close to my home. I have no idea what they are actually manufactured for but I know of 7 local Ham's that have used them for their Hex-beams. They are similar to the fibreglass rods that are used on sailing boats as battens in the main sail to keep the required shape of the sail and are sufficiently flexible.

We are in mid summer in the southern hemisphere and thus I am trying to get the antenna completed and up for next month. Everything is completed except for a fellow who is welding an aluminium hub for me which should be ready for collection in the next few days.

Just as a matter of interest, the total cost here of all the parts is equal to about US$110.00 excluding the co-ax, which is the most expensive single item.

Due to the amount of leftover rod after cutting, I was thinking of making a portable 6 M Hex. I have an IC-706MkIIG but have never been on the air on the 6 M bands which I am told are not very active here. Time for change!

If you need flexible rods, try a local sail maker and see what they can provide.

Hi Keven,

Not so much that the guys on our list agree with the values you cite
below, it is that these values are taken directly from Mike Traffie's
1995 paper on the Hex-Beam. This paper is in the Files Section.

Hello John,
what frequency range are you going to work on 6m. What kind of wire are you willing to use (material, diameter and type of wire insulation). As monoband versions are easy to calculate I could design an antenna on EZNEC4+. As we in Germany have only limited (by number) licences for 6m and I'm not one of the happy ones who won in the licence lottery I'm not active/focussing on 6m.

Hi John,

I have a home made 5-bander and during the summer I had a lot of 6m QSO's. Computer model shows that 18MHz elements are working prety well on 50MHz and gain is around 5,5dBi. In my case SWR is lower than 1,8.

From: Garry
Topic: 2278 Message: 2285

Gerry. I'm not sure that lack of flexibility has any bearing on what you use for spreaders. Suppose that you inserted a small wedge under each spreader rod where it is attached to the hub thereby causeing the spreader to extend from the hub at an upward angel of 85 degrees rather than to jut out at an angle of 90 degrees. This should give a similar effect as flexing or bending of the spreaders. Then again, if you are building a single band antenna, such as six meters, you will only have the one set of elements (ref/driven) so what need is there for flexibility other then for possibly assisting to keep the wires taut? There might be any number of options for accomplishing that.

From: David Douglass
Topic: 2286 Message: 2286

Have finally started work on my third 5-band Hex-Beam.

I built the centre post last night using 32mm PVC pipe, and installed the feed-wire internally. Many thanks to Holger for his explanation on how to do this.

I've uploaded a few pictures to the files section under 'VK2NU'.

There is nothing really new here, and I suppose most of the techniques have tried and tested, although I did make the centre post a little longer than needed, so that I could house the choke balun internally just above the 20m element.

I've also taken a picture of the element attachment nuts, that I got from Holger. These are excellent for the homebrewer, and will neaten things up no end. Also, in the same picture is a shot of the liquid electric tape I'm using to seal up all of the element and coax attachment points. I've only just come across this product and it seems excellent (and made in the USA I believe).

I'm using the same hub as my last Hex-Beam, which consists of the end from a drum of coax (idea courtesy EI7BA). Elements will again be good old Tasmanian Oak dowling, but this time sheathed in thin walled pvc pipe for extra strength.

Work is now on hold pending arrival of # 14 copper wire from the US. Like decent beer, good antenna wire is impossible to find in Australia.

Regards All

David, VK2NU

Holger,

Thank you for your reply and kind offer.

I would be working mainly on 50.200 (the South African calling frequency) and thereafter moving up a few kHz. I will be using 1.5mm dia. stainless steel multi-strand wire which is NOT coated. This appears to be what most Hams are using here next to the sea as copper corrodes rather quickly.

Hello Dale,
if you download the zip with the EZNEC file you will find a second
file which has TXT-format and can be seen with every editor program.
This file includes a summary of the dimensions, distances between
band elements and isolator data for this antenna.
If the files are not in this file section please check my webpage.
The "reflected W beam" page has a link "data & files for download".

regards Holger

PS: John, ZS1JNT, I have not been able to calculate the 50MHz model
yet. I had to work a lot during the last days.

Hello John,
you will need to do some homework yourself if you need the design. I have downloaded a file in the file section under DL7IO called "dl7io-40-4-without20m.pdf" This shows the EZNEC results with 20m elements removed.

Yes, I have used the copper plumber strap in two 5-band
antennas. I soldered brass bolts at appropriate spacing along three
lengths of strap, two for feeding, other for the reflector. Drilled
matching holes just a tiny bit oversize for the bolts, and slipped
the strips inside one and one-half inch pvc pipe, wiggled the strips
until the bolts came through, then held them in place with a washer
and nut. Later, the wire elements were installed with another washer
and nut. No problems experienced, and I feel good that the straps are
out of the weather (rain, ice and snow at times). By the way, I
feed one of them at the 10 metre element, and the other one at the 17
metre element. Naturally, the tuning was a little different for each,
but the results of using them on the air seem to be the same. Nice
antenna in a compact space.

regards,
Doug VE3CWO

2298. 5 bands Hex-beam ????

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-01-11 13:14:44 UTC
From: Giorgio
Topic: 2298 Message: 2298

Hi to all.

I am building my 5 bands hex-beam with the help of the DL7IO documents, found in files section.

I am doubt with elements dimension: using measures from reflectedW-design-en.pdf, applied to hexbeamcalcv3.xls, it seem for example, the driven elements are calculated for:
28,741
25,732
21,591
18,463
14,218

What is most accurate, using measure from .pdf or .xls ?

73, Giorgio iv3ddm

Hello Giorgio,
hexbeamcalc... is a tool to estimate the values for monoband versions. The low impedance line conecting all radiators of course has an influence on the dimensions. You better go with the dimensions from the file!
regards Holger

2300. Mounting below a vertical.

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-01-13 22:46:34 UTC
From: mga620000
Topic: 2300 Message: 2300

I bought the parts to build a 20 m Hex about three months ago. I machined a hub from a chunk of nylon and am using fiberglass poles.

My question has to do with mounting. My primary antenna is a Gap Titan which is acutally a vertical dipole. It needs no radials, so can be mounted at any height. I am getting ready to install a 30 foot aluminum tower for the veritcal, and wondered if the hexbeam could be mounted below it with the 1-1/4" mast for the vertical running up the center tube. A rotor would be attached to the mast and rotate the entire assembly.

Any thoughts?

2301. 6 Band Hexbeam

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-01-15 14:18:58 UTC
From: John
Topic: 2301 Message: 2301

Hello Hexbeamfans,
Its a while ago that I posted. Yesterday I added 6M
driven and reflector-elements to my HEXbeam, and aligned it with AEA-
antenna-analyser and looks very good to me. I bought black and red
wire in a near garage. Its 3,5mm innerdiameter and 5mm with
insulation. I used the dimensions from Holgers (DL7IO) monoband 6M-
HEXbeam, and after 2 times pruning (I fold back the wires) my
dimensions are exact 10cm (almost 4inch) smaller then from Holger.
I'm using a separate coax to feed the 6M-part of the HEXbeam.
I made a submap "6 Band Hexbeam" in my photomap "PA2JJB". Those
photos telling you more then lots of text. The first 2 photos showing
the damage when my HEXbeam come down after a hugh storm in june 2004.
I placed alu-profiles under the bamboos to strenghten them, and with
the big storm from last week over England, Holland and Scandinavie
only the 12M-reflector was broken, but the antenne itself is still
standing. I rotate the antenna by hand, because my TV-rotator was
also damage in the june-storm. Now i use 2 guidelines to give me and
my wife a better feeling when were alseep lol.

Lots of fun with this marvelous antenna and hope to hear from your
experiments..

I have put a page about my wonderful homebrew 20/17 meter hex-beam on my website. It has some significant differences from others I have seen both in construction details and feed method. There is also information on how to make a coax choke balun.

This is the best antenna I have ever had, and this is my 50th year of hamming! I have had great success with it. Please Email me with your comments and any questions.

To get to the page point your browser to

2304. 30-40 m Hex-Beam

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-02-02 01:28:30 UTC
From: w4wb
Topic: 2304 Message: 2304

After a long wait, I received my customized Hex-Beam for 30 and 40 m with the 40 m portion tuned for the CW sub-band. Mike Traffie used this antenna to experiment with some new/modified ideas to enhance the performance of the antenna. This is the first 30-40 m Hex-Beam shipped (he made one for experimenting a while back I understand, but then it morphed back to a 40 m HB). Both dual and a common feedline approaches were evaluated. The common feedline approach proved superior. From Mike's report, the antenna really sings!

All I have to do now is to install the tower I refurbished last year, get a suitable rotor, and then assemble and install the Hex-Beam. However, it is winter and that makes the opportunities to do the installations iffy. WX here has been like a late fall recently, not at all like that shown in the beautiful photograph Holger posted of his QTH.

My hope is to have it installed in time to work the Peter I DXpedition this month, but ... In any case, I will report upon my observations of the antenna's performance after I have had a bit of time to play with it.

My dream of having Hex-Beams covering 6 through 40 m is almost a reality thanks to Traffie. :-)

73,
Barry W4WB

Hello Barry,
this sounds good. Send a picture if it is installed. I know you will like it! My log has mainly 30/40m entries since last summer. Try to bring it up to 60 feet or more and it will be a DX hammer.
Is the antenna feeded from the top (at 40m) or at the 30m element?
Is there a chance to get more details of the antenna like element sizes, spacings etc. to simulate it?
regards Holger

From: w4wb
Topic: 2304 Message: 2306

Hi Holger,

I will try to post a photo or two of the antenna when it was at Traffie's place. Seems that my tower installation will limit my height to about 55 feet. Not my desire, but that is what it will be. I agree that 60' would be nice, maybe a bit more.

It is fed like his other antennas ... from the top. I have no constructional data to provide. This is a custom and experimental antenna he optimized for my requirements. I expect that a slight variation will soon be available from Traffie as a commercial 40-30 m Hex-Beam ... bet it will be called the HX-4030i. :-) I have no idea what the production antenna price might be.

From: Dave
Topic: 2307 Message: 2307

Hello all,
New to group and interested in 40 m monoband hex beam design. Do anyone have one so I do not have to "rebuild the wheel" :)

Tnx in advance,
Dave W1CTN

2308. Re: 40 m hex

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-02-20 19:20:57 UTC
From: dl7io
Topic: 2307 Message: 2308

Dave,
If you check the databases you will find datas for mono- and multibanders with 40m included.
Here are the values for a design I calculated and built already:
half driven element: 1133 cm
half reflector element:1110 cm
insulator radiator/reflector: 27/21cm
or see message no. 1986
The other designs can be found in later messages or on my website:
www.dl7io.de
regards Holger

PS. I worked a few hundred W/VE stations last night (ARRL-test) on 40m. If I could catch one of you...thank you for the QSO.

PPS. I'm looking for a prototype tester for a 80m design. I will do all the antenna construction work but need somebody with a QTH for this size and a tower of min. 30m to install the antenna. A location in Germany would be preferred. A tower with the possibility to move the antenna easy up and down would be ideal. Than we could test different multiband designs e.g. 80/40/30m...

Contact DL7IO he has a full parts list and sells just what u need but you
will still have assemble it all measurements are in the files area of the
yahoo group complete measurement in metric in Dl7IO folder look there.
N9IWW
If you want it from the usa then go to http://www.msg4u.com
Since your in the uk go to your local fishing shop find some poles 9-10
meter long these will work just fine telescoping kind. Need 6 each.

2321. Moxon vs Hexbeam ???

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-03-08 12:40:24 UTC
From: K0PYK
Topic: 2321 Message: 2321

HexBeamer's
I have been thinking about a 17 meter antenna...Did
some research at various sites. Both moxon and hexbeam
came up as possible choices for wire beam antennas.
The info suggests that the moxon has a slighly better
gain and improved f/b. I like the concept of a light
beam on the tower with my tri-bander.
I look forward to you thoughts.

Hello Tom,
the gain difference is marginal --> 0,x dBi.
F/B is much better on the moxon and of course for a single band the
mechanical part is much easier to handle.
Multiband designs are harder to find.
For more details I recommend: http://www.cebik.com
Go to "tales and techniques" and find many good articles on moxon's
and other kinds of antennas.
regards Holger

2323. Moxon vs Hexbeam ???

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-03-09 09:36:48 UTC
From: David Douglass
Topic: 2321 Message: 2323

Tom,

I'd have to say that on performance, the Moxon would be the better choice, due to its excellent FB ratio. But if size, mechanical strength and wind loading are important considerations the HexBeam would be clear winner.

If your thinking about putting the 17m below your Tri-bander, it would also be more straight forward with the Moxon.

Paulo,

Also check the Coax is good, I had a problem with my Home Made 5 Bander, I could not get aceptable SWR on 15M, It took me 2 weeks of hard work before I swapped out the coax to find everything was OK after this.

I thought the first Coax was OK as it worked fine on another antenna, but after chaning it for a similar length cable the problems were gone.

It's worth a try if all else fails.

I hope you get it sorted soon,

Hi Paulo,

My first guess is that Holger is correct. Since you have the commercial version of the Hex-Beam, the simple way to check to see if the elements are reversed is to look at the color of the connector going to the center post. Red is for the driven elements and black is for the reflector. This wouldn't be the first time anyone mixed them up by reversing or by having one red and black for each the driven and reflector elements!

FWIW, if you have the colors matched, then I would quickly measured the lengths of the driven and relector elements to be sure the color coding was correct from the manufacturer. The red elements should be shorter than the black elements.

Dear friends..
I can not still solve my problem:
15 meters still 3.1...3.2 SWR

The FB does not exist, i mean i made aqso today with i.e GP0 and TM6 UK and france and their signal was with beam in their direction 5/9+10... then i went upsatairs and i moved the antenna to 240º their signal just the SAME.

There is F/B in this antenna....I worked TO7C French Guyana Dexpedition with 37º is this possible..they turn to 240 º and his signal was the same.

What do i do??

Why the antenna is soooooo difficult.....????

I will put some photos on my file so you can see and help me ok?
I took a few moments ago..with the antenna on the roof..

I feel very sad abou this

My friends..just to tell you that i have made the measures of both wires : the black wires are bigger around 6,5 cm than the red..Is this info going to help me..
Count with your help to solve this problem..because the manufacturer is not helping at all so i just can count with you my friends..
waiting to hear from you..

Another thing i took all wires of 15 meters and has not affect the antenna in a negative way regarding SWR....

Paulo,

This is interesting information. The lack of F/B indicates to me that you are not radiating with the Hex-Beam as it is designed. The Hex-Beam has excellent F/B (as well as SWR) when installed correctly. Are you certain that your coax is okay? I have seen folks radiating from broken coax before.

Something is very wrong with the installation Paulo. You are having the behavior of a vertical antenna. I am aware that you sent an email to Traffie and commented that the signal levels from the Hex-Beam are 3 dB DOWN from your dipole (although you have not shared this information on the list). Again, that indicates that something is very wrong with your installation.

2337. My Hexbeam Installation

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-03-15 04:04:26 UTC
From: Bill Metzger
Topic: 2337 Message: 2337

For those that might be interested, the following link will take you to images of my Hexbeam installation. The antenna works terrific. One interesting thing noticed about it is the very low SWR (1.5 or less on 20 and 1.1 on all other) and the reports I've received. In virtually all cases a DX station hears me clearly even though I can barely can hear them. Using an Icom 756PROII either at 100 watts or via an Alpha 99 at 1 KW. I'm very impressed with the performance.

Hi Gerry..
Please lets see if i understand english:what do you mean by the
elements(Spreaders..or the different wires that give shape to the
antenna 2 red and 2 black for each band?..If its so ..thats what i
did: the black elements are around 6.5 com longer than the red ones
(2).i took the 4 4 wires brought down to the QTH , and i got that
results.Is this what you mean? Thank you for your support.

From: Jim Balls
Topic: 2333 Message: 2341

Paulo.

OK
The wires are the elements 2 red & 2 black for each band
The Supports are the Spreaders

So the 20M elements are at the top of the antenna, then 17M then 15M then 12M then 10M OK

All the red elements are the Driven elements are should be connected to the same side of the support pole in the center (These must be where the coax connects to, check this out with a continuity tester or multimeter to ensure they are all connected, one row of connectors the the center of the plug and the other row to the outer of the plug.

Now on the other side of the center pole are the reflector (Black Wires) connectors again all the Black wire must be connected to this side of the center pole.

Is all the above clear and correct, come back once we have established this.

Also are you using a Coax Balun, is it the coiled coax on a former or is it ferrite beads?

Regards,

Jim M0CKE

Paulo after looking at your pictures I am as confused as you are. I saw nothing in those pictures that shows anything wrong. I believe that maybe you need to look at your coax as the possible source of your problem.

Hello Paulo,
please tell us the height your antenna has above the roof while you
made those tests? Have you any pictures made whith the antenna
installed at the final position?
regards Holger

Paulo,

Thanks for the photos. Here are a few comments.

1. You have the coax on the wrong side of the mast. It should be on the "cold" side. Read your instruction sheets yet again.

2. I suggest that you take an Ohm meter and make a few measurements.

a. disconnect the coax from the antenna.
b. place one probe on the driven 20 m element (hot side or center conductor) and the other to the center of the antenna connector. It should show essentially zero Ohms.
c. leave the probe on the 20 meter element and then touch with the other probe each of the other elements on the hot side. Each should show essentially zero Ohms.
d. repeat on the cold side (go to shield on antenna connector this time).
e. put probe on 20 m reflector and check to see if element have connection from one side to other.
f. check to see that reflectors are NOT shorted to driven elements.

3. Now WITH THE COAX AT THE ANTENNA STILL DISCONNECTED, see what your SWR is on the different bands. You will not be the first to have foul feed line.

Please advise of your results Paulo. There is something wrong with the setup ... antenna construction/assembly, coax, etc.

GL,
Barry W4WB

Topic: 2346 Message: 2346

The experience was done in a mast with 5 meters from the house of the roof.
I bought a new coax cable this afternoon..its BIAS..low looses and conditions are a bit better..in alll bandas ..clear..but my problem is still 15 meters..and i get station from North Europe with the same signal with reflected side or driven side to them...it isa pitty you are away otherwise i could make a test with you..

Holger please tell me what happens if i put my antenna at 15 meters high?? In my tower..

Tks a lot to you and all friends from this HEX group..i fell real HamRadio spirit and frienship here....i am going down but you do not let me go down..you want to save me with all the knowledge you have!! Thank you all of you for your concern.
Take care..and lets see if my Hexproblem can be solved..even if i invite Holger, Barry , Doug... to spent a few days in the Algarve.(good shellfish and red-green wine..grilled sardines..this is the place)....then i will be sure my hexbeam will be 100% :-)

Paulo

Anybody notice in the photo, that one of the reflector wires looks
loose or not connected properly? I am talking about this pic:
antena 110---1
I also noted on the pic, the coax is practically laying on the
reflector elements. Just a thought.....

I did bough the BIAS low looses Coax cable this afternoon ..a bit
improvment was felt..the only thing i did not try was the shock with
the ferrites ..which i bought from Palomar Engineers...
I will put the in a few moments ..2 radio hams are coming to help me
watch the situation..its going to be a long night..they are used to
deal with cubical quads so i aspect a bit help from them ..we will
take all wires ..and start from the begining..
Best 73´s

2350. RFI via Rotor Cable?

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-03-15 20:21:31 UTC
From: Brad Johnson
Topic: 2350 Message: 2350

Hi All...

Been enjoying my 5 Band Hex Beam for a couple of years with no problems and have been very pleased with the performance. I recently acquired a new transceiver and have begun having problems with RFI in my headphone circuit...odly enough, only in that circuit. Apparently this particular transceiver is more sensitive to RF than others I have been using.

I've been trying to track down the source of the RF that is getting into the headphone circuit and have come up with a possible suspect... the rotor cable. When on the Hex Beam, this problem only occurs on 20 meters. The coax is choked per the manufacturer's recommendations. The SWR is low and to the best of my knowledge, the coax cable is in good condition. I can't recall the exact length of the rotor cable run, but I think it is approximately 150 feet. The rotor cable is tied to the coax for most of the run. I am using a Channel Master Rotor with a four conductor unshielded cable.

I hope to obtain a clip on RF ammeter to confirm that the rotor cable is the culprit, but until then I was wondering if anyone might have had a similar problem? I believe many of you are using the Channel Master rotators with the Hex Beam.

I can change the severity of the RFI by moving the rotor cable around and bringing it into closer proximity with coax and power supply cables at the rear of the equipment.

I attempted choking the rotor cable as it entered the shack, but it didn't seem to effect it. IF it is the rotor cable, I'm guessing the RF current is being induced by its long run next to the coax, or it is entering at the rotor end and should be dealt with there.

I would appreciate any suggestions. A few others with this transceiver are reporting a similar susceptibility but until the manufacturer acknowledges that they might have a design shortcoming, I need to work it from the source.

Thanks and 73,

Brad

Hi to all! First of all I'd like to thank you all for such a great web site with all of the helpful info on hex beams. I am home-brewing one and was wondering about lightning protection. Will it throw off the performance of the antenna if I run a small ground wire from just above the center support (highest point) down to a ground rod or how else should one deal with lightning protection? Thank you in advance for your advice. Randy. WV9T

Hello Brad,

I recently moved from California to Florida. When I was in California, I always had rf problems up the kazoo. The water table was so low there it was impossible to get good grounding. When I got my first Ten-tec rig (the Jupiter) I had even worse problems. To solve the rf problem on transmit, I added a secondary ground from the input plug ground pin on the rig to a chassis ground inside the rig. This along with a couple of caps on the loudspeakers in side the earphones cured the rf in the headphone problem. Later I moved my shack to a small building outside. There I had problems on 20 meters with my Icom. The solution was to run a secondary ground with a 4 gauge wire from the shield connection on the antenna directly to a ground rod right at the base of the tower. The rf on the rotor wires sounds like a common mod problem.

Twenty meters really requires at least a half wave length above the ground to avoid problems if you are running power. Surprisingly here in Florida I can run legal limit with the antenna only up at 30 feet. Hex-beams tend to act a bit as cloud warmers as well as beams. This is kind of a unique feature because its great for round robbins with stations all over the country as well as dx. This I consider a nifty feature not available on conventional yagi's. We had sort of a mini-dxpedition when I moved out to Florida via driving. Old Claude (kd6cys) was copyable all the way from California to Florida. Even though we were just running a ham stick.

Hi Randy:
I use a Polyphaser Coaxial Impulse Suppressors or Lightning
Protectors in all my coax and rotor connections.
Will be a good idea that you buy those little gems to protect your
equipment investment.

http://xxx.surplussales.com/Antennas/polyphsr.html

Replace the XXX for WWW. I don't think is a good idea direct links,just
easy way for hacking.

Subject: Re: [hex-beam] RFI via Rotor Cable?

Hello Brad,

I recently moved from California to Florida. When I was in California, I always had rf problems up the kazoo. The water table was so low there it was impossible to get good grounding. When I got my first Ten-tec rig (the Jupiter) I had even worse problems. To solve the rf problem on transmit, I added a secondary ground from the input plug ground pin on the rig to a chassis ground inside the rig. This along with a couple of caps on the loudspeakers in side the earphones cured the rf in the headphone problem. Later I moved my shack to a small building outside. There I had problems on 20 meters with my Icom. The solution was to run a secondary ground with a 4 gauge wire from the shield connection on the antenna directly to a ground rod right at the base of the tower. The rf on the rotor wires sounds like a common mod problem.

Twenty meters really requires at least a half wave length above the ground to avoid problems if you are running power. Surprisingly here in Florida I can run legal limit with the antenna only up at 30 feet. Hex-beams tend to act a bit as cloud warmers as well as beams. This is kind of a unique feature because its great for round robbins with stations all over the country as well as dx. This I consider a nifty feature not available on conventional yagi's.

I don't understand why the takeoff angle of a Hexbeam would be any different than a yagi or quad with their current loops at the same height as the Hexbeam. My understanding is that the far field takeoff angle is a funciton of classic ray reflection theory- regardless of the emitter.
Can someone inform me or send me some NEC models?

Tnx,

Dale W4OP

Subject: Re: [hex-beam] hex beam lightning protection

Hi Randy:
I use a Polyphaser Coaxial Impulse Suppressors or Lightning
Protectors in all my coax and rotor connections.
Will be a good idea that you buy those little gems to protect your
equipment investment.

http://xxx.surplussales.com/Antennas/polyphsr.html

Replace the XXX for WWW. I don't think is a good idea direct links,just
easy way for hacking.

Best Regards
Comsat de Mexico

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-03-19 09:01:37 UTC
From: David Douglass
Topic: 2359 Message: 2359

Just uploaded a couple more pictures to my folder on the Yahoo Site, showing progress to date on Hex-Beam #3.

I now have all the parts and just need to attach the element to spreader connectors to all of the elements and align them so that the elements are taught and as horizontal as possible.

All elements are cut to size and ready for installation.

Total cost will come to about $400AUS, with the bulk of this having to get fibreglass poles from Cubex in the US, and wire for the Wireman in the US. I've also spent about $70 on hose/compression clamps.

Barry, I notice that the photo section is filling up, so if you would like to delete my old folder/photo's (VK2DPD), for my previous 2 Hex-Beams, go ahead. I would do it myself, but can't remember my all log in details prior to changing my call.

Regards all

David, VK2NU (ex VK2DPD, M0DPD)

Hi David,

I removed your old folder as you requested. Guess I need to go in and clean out some more. Maybe some of the members will take a look at their photo folder and delete aged or unneeded photos so that others can have a bit of space. 30 MB is all Yahoo! allows.

#3 HB is looking good. I have one question however. When looking down into the center support, I noticed that you have your ferrite beads just below the SO-239. Seems that this isn't a good place to locate due to potential saturation of the ferrites. When I have played with placement, just below the hub did the trick. I know you have done a lot of experimentation, so I would value your comments on this.

BTW, is the rotor other than the "armstrong" model for this version? :-)

Topic: 2359 Message: 2363

Hi Barry,

Thanks for getting rid of the old pictures.

Regarding the ferrites, I do have these directly at the feedpoint of the antenna, and this seemed like a good idea at the time. I have always used this method with my wire beams, and used ferrites directly at all feedpoints on my Hex#2 (5 band individual feeds). On my Hex#1 I used a coax coil/choke at the feedpoint and had no issues, but maybe that is because I only used low power (100w max) ??

I suppose I'll have to give it a whirl and see if I have any problems, but would be interested to know if anyone else has tried this and had any issues?? I know conventional antenna wisdom states that you should install them at (or a close as possible to) the feedpoint, and I always stuck to this. Once I have it up and running I'll make further comment, but it would be easy to remove the ferrites at a later stage, and install further down the feeder.

On the rotator, I've gone to the expense of buying an old CDE AR22XL, which I've restored for the job, so I'm hoping this is heavy duty enough? This is my first ever rotator, so looking forward to being able to turn the beam from my chair !!

I'm hoping this all goes OK, as this would be the most I've ever sent on an antenna, although having to get most of the parts from overseas didn't help. It cost just about as much to ship the spreaders from the US, as it did to buy them, but it was still cheaper than sourcing these in Australia. Likewise, decent antenna wire is impossible to find down here.

All the best

David, VK2NU

Hi David,

Thanks for the clarifications. Am sure you will enjoy having the rotor!

I will be interested in your results with the beads. Just think about where the high currents/fields are located.

You certainly make a case for why we that live in the USA should be grateful to have such easy access to and relatively low costs for materials to build antennas and such. It is too easy to forget this. I have been out of the USA where it was very difficult to located anything and it took weeks to order and receive parts.

Worked FT5XO yet? No joy here yet, but maybe tonight on 20 m.

2367. Homebrewing a Hex

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-03-21 23:21:18 UTC
From: W1GQL
Topic: 2367 Message: 2367

I encourage anyone interested in building a hex beam to check out my web site at http://www.midcoast.com/~w1gql/hex.htm

My hex design varies from the traditional in a couple significant ways that make construction easier but do not negatively affect performance. I do not make the wires in the elements a structural part of the antenna, but rather suspend them in a framework. I also use a solid wooden rod for the center post and feed the the elements with separate coax lines. Check out the webpage and please let me know you have been there and what you think.

The antenna has help up wonderfully through a rough Maine winter and allowed me to work the world, hearing things I never heard before in 50 years of hamming.

Dave W1GQL

2368. QUESTIONS was: [hex-beam] Digest Number 668

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-03-22 01:18:29 UTC
From: RFImages
Topic: 2368 Message: 2368

Why do the elements on a HEX Beam need to be bowed?

Why can't you just lay them out flat on the spearders?

Has anyone ever mounted a HEX Beam Vertical? It seem like
a vertical mounting would work exceptionally well, like a
vertical dipole.

Also, it seems to me that a 17 through 10 meter HEX Beam
would be a very manageable size.

Has anyone ever experimented with a sigle element HEX Beam?

Bill

Bill,
I would guess if it was your wish to have a one band beam, spreaders could be horizontal, but if you want multibands, curving the spreaders places the elements on a different plane, since their lengths vary, and thus prevents their presence from interfering with performance on adjacent bands. If you only want a single band antenna you give up the big advantage of choosing a hex beam.Try one, You'll like it!

Dave:

This is great. I've been thinking of how to do a 40m version and will use this as a base. I'm assuming the dimensions of your 20m version can be scaled by a factor of 2 to get the correct 40m dimensions (?)

2372. Re: Making a homeBrew Hex Beam

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-03-22 21:42:06 UTC
From: dl7io
Topic: 2365 Message: 2372

Hello Bill and a few others as well,
of course can we help! And we will if you have any problem, like we did for Paulo, who's beam is playing well now.

But please: if you are serious interested, you should first read the posting on this forum. This would give you a lot of helpful information and links you need. And probably you will find answers on most of the questions you have in the beginning.

You will find links and information for mono- or multiband designs in all variations you may wish to build, simply by reading the postings.

It is only a little work compared to developing or designing an antenna and I guess it is the minimum we can expect from everybody here.

Sorry if I have been to direct.
Regards Holger

Topic: 2374 Message: 2374

Open Letter to all readers..

I want to thank to the excelent radio hams that in moments when i fell i wanted to quit of the HEXBEAM assemble, i felt weak and wanted to give up..they gave me strengh to go on...and i made it!!!
These SPECIAL Radiohams are :
W6HB DOUG;
W4WB BARRY;
DL7IO HOLGER;
OTHERS..
I AM VERY PROUD TO BE PART OF THIS FAMILY.....
These Hams they help me from their heart..they did not rest untill my problems were solve from the shockof toroids....to the PL.coax cable...everything... they check and check...check again to HELP ME....
THEY DID NOT ASK ANYTHING IN RETURN....THIS IS RADIOHAM SPIRIT AND REAL FRIENDSHIP!!!!!!THANK YOU FROM THE BOTTOM OF MY HEART...NOW I AM READY TO HELP TO :-)))?????

BUT NOT ALL WERE FLOWERS, UNFORTUNELY.....

I feel sorry for the lack of help from the manufacturer..
I am sorry MIke but you were not helpfull...as you should be.....
may be in future you can change your policy and think a bit more of your clients has people who need your attention..not only USD are important....

CT1ITZ
Paulo
PS: I will post now the photos of my station.....:-)

2375. Looking for DL7IO

Yahoo group: hex-beam (2001 — 2006)

From: ve3xj
Topic: 2375 Message: 2375

A couple of weeks ago I sent and e-mail to DL7IO enquiring about prices for homebrewing my own hex beam. Not having received a reply, I sent another e-mail requesting a reply last weekend. Still nothing. Perhaps I did not send it to the correct e-mail address, so can I hope he will read this and let me know if he got my messages.

Paulo,

Your Photo folder is empty. THere is aome space available to upload your photos. Please BE SURE to adjust the file size to as small as you can to minimize utilized space in the Photo section.

Remember that you have to be logged into the Hex-Beam Group web site before you can upload the photos.

Installation looks fine now.

From: hex-beam@yahoogroups.com
Topic: 2380 Message: 2380

The following hex-beam poll is now closed. Here are the
final results:

POLL QUESTION: What are the reasons you bought,
homebrewed or are generally intetested
in the hex-beam? Please select
all that apply.

CHOICES AND RESULTS
- Wanted beam antenna with gain on 17, 34 votes, 5.48%
- Wanted beam antenna with gain on 15, 34 votes, 5.48%
- Wanted beam antenna with gain on 12, 30 votes, 4.84%
- Wanted beam antenna with gain on 10, 34 votes, 5.48%
- Wanted beam antenna with gain on 6, 6 votes, 0.97%
- Didn't want to put up a tower, 22 votes, 3.55%
- Low visability, 25 votes, 4.03%
- No traps, 39 votes, 6.29%
- Broadbanded, 27 votes, 4.35%
- Low maintenance, 31 votes, 5.00%
- Cost per band, 16 votes, 2.58%
- Quality of construction, 20 votes, 3.23%
- Suitable for portable opertions, 10 votes, 1.61%
- Received as a gift, 0 votes, 0.00%
- Single feedline, 38 votes, 6.13%
- Reputation, 16 votes, 2.58%
- Referral, 3 votes, 0.48%
- Other - share as post if willing, 0 votes, 0.00%
- Small footprint, 41 votes, 6.61%
- Light weight, 48 votes, 7.74%
- Low wind load, 45 votes, 7.26%
- Requires light duty rotator due to symetrical shape and light weight, 32 votes, 5.16%
- No tuning required, 27 votes, 4.35%
- Wanted beam antenna with gain on 40, 9 votes, 1.45%
- Wanted beam antenna with gain on 20, 33 votes, 5.32%

2382. Photo Upload

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-03-25 08:20:10 UTC
From: vk2nu
Topic: 2382 Message: 2382

Hi All,

Have just uploaded a couple more pictures to my folder, this time detailing the element to spreader attachment.

For this I've used 2 inter-laced hose clamps. The first is attached to the spreader and the second holds a short length of fibreglass tubing (tent poles cut to 4cm in length). To protect the fibreglass from the hose clamp, I have a short length of plastic hose around it.

This allows the elements to travel through the attachment point as the the attenna moves in the wind.

As you'll see from the pictures Im using traditional end insulators for the elements. I would have prefered an arrangement similar to the Traffie Hex, but couldn't think of how to come up with this, and didn't want to use the plastic electric screw terminals that are shown in Holgers building instructions, as I didn't think this looked all that strong !

If the weather holds out over the Easter weekend I'll assemble in the garden and do some initial tests at low level before placing on the roof.

Hope you guys in the US are hearing FT5XO OK ??

Regards

David, VK2NU

Hi ....

I am new to the group and am enjoying this hexbeam adventure a lot ....

I was wondering if anyone has any experience using fishing poles which might contain graphite ...they seem to be fiberglas, but they do have graphite stamped on them..... otherwise, theyre perfect .... 10 ft long, great flex ... also they're blanks (no eyes or stuff on them) .. i have 10 of them ....

does anyone have an idea about this

tnx and 73's .... gerry .. KE5DWN .. near San Anton, TX

2386. Very happy with my HEX performance

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-03-28 00:04:06 UTC
From: Paulo
Topic: 2386 Message: 2386

Hi Guys i want to tell you how i am with my Hexbeam performance..i can listen much better than a rotary dipole..i was very ceptical concerning this antenna...but now i will not change it for another..its small and works well speacial on DX..
The heigh is 18 meters..the manufacturer says 12 meters..but i do not want my Hex beam to local QSOs..this weekend i work everything..Laos..Taiwan..S.America..so i do not understand why he says to put it 12 meters..if you are a dxer like me ..put it higher as possible..and you will see ..everybody i listen i work..

I will try to put some new pictures of my hex and rotary dipole..there is no interaction between them ..i put it 90º from the hex direction and no SWR..nothing...by the way the SWR ..check well goes from 1.1 20 meters to 1.4-1.5 on 10 meters....

I am very happy with the performance of Hexbeam..very happy..it is much different from the rotary dipole..you were right my friends.we can not compare it..now on 40 meters i look sad because i have to fight hard on pile ups..i wish i have Known Holger before ;-))) But life goes on..
Many Hams that were here in Easter weekend (my area is the most touristical part of Portugal) stoped to take pictures..i talk to them but they joke with my antenna they say it looks a bunch of wires to put the clothes.drying.i do not mind.i told them lets go dxing and you will my beauty working....i can fight on the pile ups with them...

My satisfaction is excellent special for DX.....

Thank you for your support..Doug, Barry, Holger..Diehl..and others...
My best 73´s
Paulo
CT1ITZ

PS: Lets Hope for a 10-40 meters HExbeam ;-))

By the nice look of our page..congratulations....

--- In hex-beam@yahoogroups.com, "k5jxl" <k5jxl@y...> wrote:
> Hi Ken...
1) I change and bought a very expensive Low loss cable...
2) Bought Anphenol Pls brand new.....

This was my first and biggest positive (change all old stuff for brand new) change
3) I move the cable down to the right position between the wire and red connection..near the sticker that(side that has the H) says Hexbeam..
4) Put the shock as advised.Toroids from AMIDON..the right ones;

5) The cable has to go out of SO (do not know the name..where the PL goes in")put it up with a turn UP facing the beam direction and be very carefull going down with coax through the feedline....

6) Also my problem is that she was near metalic stuff...she has to be as far as you can from metallic or glass..or other material...

7) Make sure the wires numbers from the bands are well fsten and in the right order..

Than just put it high in the sky and go for it..

I am not an expert..ok i am just telling what my friends told me to do and it works..it is good to have a Hexfamily..i felt that..when i was falling in to the deep waters..they grab me and help me.....

I put some photos of my instalation ..so if you want you can see..

If anybody wants to send me e mails..or talk to me pls fell free to to so..but i repeat i am not an expert..but pass through bad moments..and learn with those bad times and mistakes...

I wish there were an European company that could produce Hexbeams (NO COMMENTS)

2389. new photo - - NF1A hex beam in snow

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-03-29 06:06:42 UTC
From: aep002
Topic: 2389 Message: 2389

Check out the new photo I posted : SNOW (NF1A)

It shows my hex beam highlighted by fresh snow. Without the snow it would otherwise be invisible because of my camo paint. I think the moderator removed that picture a while ago because there was no Hex Beam to be seen. This new photo should be a keeper.

73,

Art NF1A

2390. Need wire element dimensions for multiband 15, 17, 20 m. Hex

It seems that today i was not able to copy any of the stations...there is the SP (Polish) Contest..:-(((..not in WARC Bands..so tomorrow i will be standing by at 17.00 UTC..its better for every body....you all can sleep a bit later on..:-))
Sorry i was not counting with this contest..also at around 17.00..i check the propagation is fine on 18119,2..just listening to US station 5/9..but are not Hexbeamers :-((

See you if possible tomorrow...18120.and 14120...12 meters is dead...just checked and 15 meters are not so predictable like 20 meters or 17 meters..

I also ask please make calls ..do not stand by ...call like hexbeamer ct1itz calling group....put some spots on the cluster..that would be nice..

Thank you
Paulo

Paulo,

14.160 is restricted to Extra Class amateurs in the USA. To include everyone, you need to be above 14.225. I regret that I have other plans at the sked time, but perhaps another day we can have a QSY.

Today i start a QSO with W6HB Doug around 17.00 on 17 meters..we tested the FB..signal reports..it was possible to listen with 5 watts between 2 Hexbeams from Portugal and California..let me tell you that the qso was made barefoot 98 % of it..Doug..beat the signals from many US Stations..incredible...
Tan after nore than 1 hour we moved to 15 meters and the band was excelent..the FB of the antennas was excelent 3...5 units... we were followed by a station from S. Dakota KC0SKF..Craig...but his Signal was very low comparing to Doug....

On 15 meters we had a nice surprise..ZL1FT...join us and we made a triangle...beautiful..he was amazed with the HEX performance..we did barefoot..me and Doug...

I want to Thank Doug for this excelent HAM moment..he is a really an Excelent Radioham.and friend..

we tested all we could..my antenna is in a tower 18,5 meters(see my photos) and the attack angle kick me on Dxing outside Europe..and Europe no complaints... today i worked 4 times Alaska..Sri Lanka..S.Cook Islands..etc..of course that many of the time i might use AL..

I have 5 sound files i would like to share with you.. so you could see how strong W6HB was comparing to other stations...but iam not sure if i can post them here...

Conclusion: With the Hexbeam i am not affraid to go on pile ups anymore with C3 Force 12´s .2/3 Elements yaggy beams..let them came ...and we will see... this is a big surprise for me..i do not want another antenna...my umbrella upside down..is Excelent..

PS: Lets see if in the next Sunday we can join more Hexbeamers...

My best 73´s

Paulo

2400. Homebrew question.

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-04-06 09:42:02 UTC
From: Ken Luther/KD5ZCL
Topic: 2400 Message: 2400

Is there any reason why this antenna can't be inverted so it looks like a regular umbrella?? It might be easier to build using cheap plastic tubing so you could take advantage of the natural weight/sag of the tubes.

Would putting the 20M band on the bottom and the 10 meter at the top degrade the performance significantly?

Thanks,
Ken

Ken,

It is arranged as it is to take atvantage of physics, i.e.,
gravity "pulls" the arms out and keeps tension on the wires and the
shape of the antenna. Invert and you have a bit of a problem to deal
with then. Also, having the lower freq elements higher is better.

73,
Barry W4WB

Hello Ken,
as Barry already mentioned, there is no cost advantage with umbrella-like installations as you need strong spreaders to hold the wire elements in their levels.
But usually it can be done this way. I have played with the idea to install a stack of 4 antennas in a 2 x 2 array. So inverting the antenna is possible.
regards Holger

PS. I have build and currently installed a version from 40-12m. Unfortunaly the 12m element does not work as calculated. The other elements only needed a fine tuning of 3-4 cm.
As I'm on a business trip I am not able to continue and had to delay this. Nevertheless it looks nice to have two 40m+ beams in the garden...

PPS. Barry, have you already installed your 40/30m beam?

Hi all and Bill.
I too am interested in building a hexbeam
If you look through the files section you will find DL7IO home installation. This has a lot of usefull info and details of how to build one.
You can also type in hexbeam into a search engine that will help.
EI7ba also has a usefull website
That should be enough to keep you going for a while
All the best gd dx Nigel G0VDZ

Sounds like saw the new antenna itis. AKA the inteferance if it is there now was likely there before. But they just saw a new antenna and decided it must be the cause of all there problems.The problem if there is one outside of your neighbors heads is there cheap tv's.

Hi Paulo,
It is unlikely that your TX/ANT is the culprit. Most likely this is a case of fundamental overload- and NO filter on the TX can alleviate this. You would need to diagnose the individual instances and install high pass filters and ferrite chokes on your neighbor's appliances.

Hello Paulo,

Your neighbors' tv interference probably caused by fundamental rf overload of the tv's because of low cost design with no or inadaquate rf rejection.

is your area served by cable tv or by broadcast tv with rooftop antennas? what tv channel freqs area affected, video or audio or both? is the tv feedline coax used double shield with braid over foil shield? braid shield alone leaks substancially above 10 MHz.
If commercial cable tv system, what is the condition and quality of their feedlines and drops? Do they have signal egress leakage?

each home case may require different solutions depending on ingress point into tv.
1. High pass tv filters at tv antenna and tv.
2. AC power filtering on power lead into tv consumer electronics
3. Common mode filtering via ferrite cores on tv coax both at tv antenna and at tv.
4. Current break of tv coax shield with back to back 75>300>300>75 ohm tv coax baluns that are open to dc on shield.

If you do the filtering changes yourself to neigbors electronics, you may become legally liable for work done. Depends on local laws.
Many tv and high end stereo stores/shops offer good quality interference solving and resolution.

Try going off the air for 3-4 weeks and tell the neigbors that you are off the air due to work and family requirements. Then come back on with low power 10-20 watts and slowly work back up and see if complaints return.

gl on solutions and your new highly visible antenna

Cliff N7HIY

Paulo,

Are you running more power now? If you were running 100 watts before, but now 1kw that could easily make fundamental overload happen.

You say the Hexbeam is 20m high. Is it now mounted on a tower that is on the roof, or did you move it to a different location?

Now the Hexbeam is 20m high you must be using longer runs of coax. Do the connectors fit properly? Have the connectors been installed properly?

Paulo ..

Do you know it is you making the interference .. ??

Make up some log books and get all the complaining people to fill out
the log books over the next week, compare times, bands etc with the
interference complaints to see :-

A, if it is you, or if is someone else / they are making it up
B, if it is you what bands are causing the problem .. you may find it's
only 1 band and you can work around this in the short term

Regards,

Jim M0CKE

, all I can help with is my experiances with graphite poles.
I usually put up a bits and bobs mast for a topband vertical with a
fibreglass pole at the top. It works fine. I then got a longer
11metre pole to replace the 10m fibre one
I didn't work It would not load properly and the swr was constantlly
changing as the slight brezze moved the tip of the mast.
But It works ok when it have a stright forward dipole. So I would
suggest if the wires are running accross the pole ok If running
along the pole not so good but as you already have them try it out
you have nothing to lose

All the best Nigel G0VDZ

Your neighbors might think you are the problem since they can now see your antenna. You might have to take a weeks vacation from using the radio and see if they still have problems while you were not on the air. At least you will be able to tell if you are really causing a problem. Convincing your neighbors you aren't is another matter. Maybe you can tell them it is a really big satellite dish and you don't use it for transmitting.

Allen, your leaving the station off the air was a good idea, but telling the
neighbors "it's just a sattalite dish" is not.
Good luck Paulo....N0OQ (Ed)....

2419. Hex Beam help

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-04-19 00:50:14 UTC
From: k9ge
Topic: 2419 Message: 2419

Hi All - My name is Harold and I'm in southern Indiana. It seems that I need some help on the Hex beam I've built up and from what I read on the news group you've provided alot of help to alot of people, so I thought I might impose on you for some help if you don't mind. I've built a mono band for 17 meters using 6 fiberglass fishing rods, 10 feet long, mounted to a 1/2" piece of poly at 60 degree spacing. I used 16 gauge, 7 stranded copper wire for driven element and reflector, the feed point of the driven element has 3/4" spacing and the spacing between the driven element and reflector is 1" at the center. I used the formula 6180/freq. for the total length of the driven element and 6262/freq. for the reflector, my tip spacing for the driven element is 5 1/2" on both sides and 3 1/2" for the reflector and all the elements are level in a horizontal plane. My problem is I cannot get the SWR down below 4-1 at 18.140 mhz. I'm using a MFJ 259B, the antenna resonates at about 17.160 mhz (SWR 1-1). I've tried about everthing I can think of, I've shortened the driven element, increased the spacing between the driven element and reflector, tried it at 6' and 15' and got the same readings. There are no metal objects (downspouts, gutters, furniture, pool etc.). I can get it to resonate at a lower freq. by adding a few inches of wire to each side of the driven element. I borrowed a friends MFJ 259B and got the same results. I've got a 17 mtr. dipole up and the analyzer checks it out perfectly. I've tried feeding it with RG8/U, RG58/U and RG 213 same results. I'm 75 years old here and been a ham almost 50 yrs. so I do know a little about what I'm doing and it's probably something really simple I'm overlooking, but it's got me scratching my head right now. If you could please offer some advice, it would be MUCH appreciated. Thanks - Harold - K9ge --

Harold here are some wire numbers to go by to better give you an idea of what length they are and where they are please let me know if this helps you some I ran them in eznec 4 to run plots so this should be good or very close to what you need. Visit the hex beam group in yahoo the wiil be the file there it's 2 mb's so it can't email it.

Hello Harold,

Based on the information as I read it, your driven elements are too short. Because there is interaction between the elements on the traditional 5 band hex beam the formulas tend to favor the short side. Since you have 10 ft poles, it may be difficult to lengthen the elements. I suggest adding a 15 meter setup with light gauge wire to your 17 meter hexbeam. I will bet that this brings you closer into reasonable swr's.

2425. New Operator Homebrew help

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-04-23 16:44:34 UTC
From: geocom98
Topic: 2425 Message: 2425

Hello everyone

Let me start by saying what a great group this is
excellent information. I have a couple of questions
that I have not found the answers to maybe they are trivial
but here goes I was curious about the height of the
center mast that the elements connect to I am planning on building
a 20-6 meter version and was just curious if anyone had the measurements

Also I was wondering if PVC could be used I know I saw that question
asked somewhere but I did not see the answer. I have a feeling that
the added weight of PVC over fibreglass or bamboo would an adverse
affect on the overall life of the antenna at any rate thanks again for
a great group

Respectfully,
kc0ahe

2426. 5-band HexBeam and Delta-4 coax switch

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-04-23 12:54:00 UTC
From: k0pqstevebanks
Topic: 2426 Message: 2426

Hello Everyone,

I recently finished the installation of a new 5-band (20m-10m) Hex and have measured its SWR across all bands with my MFJ 259B meter. All SWRs appear quite "normal," ranging from about 2.5 down to 1.5 depending on the band and frequency being measured. I find that connecting the test meter directly to the shack feedline connector yields pretty good results as noted above.

However, when measured through a Delta-4 coaxial switch, the Hex SWRs are considerably higher, in the range of 6.0-8.0, instead of 2.5 to 1.5.

Has anyone else had similar experiences with a Delta-4 coax switch connected between the Hex feedline and a test meter or transceiver? If so, has the installation of Amidon beads near the antenna mounting plate as suggested by others helped?

I've used Delta-4 switches with other antennas and have never seen the SWR affected merely by connecting the switch.

Thanks for any thoughts.

Steve
K0PQ

2427. Re: New Operator Homebrew help

Yahoo group: hex-beam (2001 — 2006)

From: dl7io
Topic: 2425 Message: 2427

Hello KC0AHE,
I have not seen a design for 20-6m with own 6 m elements.
But the 5 bander 20-10m has a SWR of less than 1:2 between 50-54 MHz.
I'm not working on 6m so I don't know if there is much gain or V/R.
The height of the center hub of the 5 bander is about 1,10m.
PVC is not problem for the center hub. Try to find any UV-resistant
material or paint it. If you use PVC and you will paint it it helps
to rough up the surface with sand paper before painting.
regards Holger

Hello Steve,
I have no experience with this delta 4 switch but probably there is
something wrong with the switch.
Take off all cables from the switch and check it with a Multimeter.
May be you are shortcircuiting 2 antennas?
The switch should not affect the SWR significant.
Nevertheless where do you have the SWR of 1:2,5? It is also very high.
Holger, DL7IO

Steve, You are seeing the results many have had on
hexbeams and other antennae that do not represent as
perfectly resonant match.(not that anything really
ever does!) To install,the switch you are adding the
switch itself,as well as the additional length of the
jumper, Which doesn't change the match at the
antenna,however changes how your swr bridge sees the
reflected waves from the antenna. Solving this problem
requires proper feed line lenghts (quarter wave
multiples to properly tune each band one at a time.
SOUNDS LIKE THIS IS NOT BEING DONE ON THE HEX BEAM due
to the myriad of swr questions I keep seeing pop up.
Once a resonant lenght of line is placed ant the
antenna is PROPERLY tuned then any length of line can
replace the resonant line and the SWR will not change
enough to matter.

Mike,

FWIW, the SWR is the same at any point along the feed line if you
don't have a common-mode current on the outside of your shield. A
simple test is to see if the SWR of your antenna system changes at,
say the transmitter, whenyou change the length of the feed line. If
it does change, the common-mode matter should be addressed.

Thanks for the responses I have recieved I have gone ahead and ordered
the spreaders (bamboo basspro shop 14ft bamboo rods $3.97)
for a final build in the meantime I went ahead and built one using PVC
since I had it one hand and since I am impatient and like to
experiiment with antennae. The construction results using PVC were
shakey at best but as I added all of the elements 20-6 meters it
became much more sound the whole thing wieghs about 17-20 pounds that
is using 1/2 inch PVC and number 12 wire with a 3/8 plywood hub..
I have not yet had the opportunity to test but I have my fingers
crossed for good results.. Next I will begin on the permanent version
but I think that I will keep the PVC version for portable and field
day use...

73 and thanks again for all the responses and solid information

This post raises a question in my mind. If you use a single feed on a 20 - 10 meter hex do you want a multiple of one of the bands for your feedline?

2433. Spreaders from telescope fiberglass fishing pole and source

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-04-25 12:05:17 UTC
From: Kevin Adam
Topic: 2425 Message: 2433

The other day I was in a sportsman store called Gander mountain and they have fiberglass fishing poles that telescope different sizes up 20 feet these would work okay but the cost if your penny pitching is a little high come to dollar a foot per pole, but they were nice fishing pole would make good hex beam, from them up to the last 4 feet that is to flexible.

Hi My friends..

I am so happy with performance of the HEXbeam..wish it was all hapiness, but unfortunely it is not..i am a lot of complaints from neighbours, when i TX with the HEX some of them cama and knock in my door..
The antenna is at 21 meters from the roof (70 feet) .you can see my photos.
I have the torroids from amidon just under the plate..it seems the HEX is radiating down a lot of RF instead to the atmosphere..

Does any one of you my friends..can help me to solve the problem,plsss!!!

I am really tired onf this situation.
I have a Low Pass Filter from Kenwood 1KW
2 Line isolaters.
1 Commom mode Filter in the back of my amplifier : Ameritron 800
New Coax Type L400..

Do you know any product that you can tell to me so i will be sure its not my problem..Whatever it costs ..so i can have some peace of mind..pls.
Please Help me.....other wise i might have to go to a Multiband rotary dipole..but i like so much my hex beam..even today i fight on Big..Big..pile up lots of EU stations on 20 meters with Guam AH2..many guys usinf TH7/11..Force12..and i 2nd call he was answering to me !!! I want to keep my hexbeam..!!!
Pls guys you help so much in the past ..i need you help now..i am very sad with this problem of HEX....

Paulo please go check all your coax for rf leaks since your higher you must have added more coax you are most like have the shield leak at the connector. The best way to check for rf is with signal strength meter have another person key radio place the signal meter next to the coax connector you will find that there is leak from bad solder connection where the shield is connected to the connector please try this it should help the best way is to have solid piece of coax to antenna from radio to antenna no breaks or add on pieces.

Paulo,

I've read all your postings and the good information posted by others. Quite honestly, I am puzzled by your RFI problems. Your newest message notes a coax box switch. In looking at your photos I see some sort of a large element directly under the Hexbeam and what looks like a balun and other stuff right below the hexbeam. I'm not sure but could all this other equipment and wiring be picking up some RFI and re-transmitting it creating the RFI in your neighbors home? If you have another antenna mounted just below the Hexbeam (looks like you do) that may be the problem. I would suggest you make a clean hookup, direct from the Hexbeam (using the torroid chokes etc.) directly to your transmitter/amplifier and see what happens. Also, you might want to ground the other antenna when you are not using it. I have used several antennas over the past two years and found the Hexbeam to be virtually RFI free compared to the others. Of all the messages on this reflector, you seem to have the only RFI problem.

Good luck.

Hi Paulo,

by changing height of your Hex you increased also the lenght of
rotator cable and it is possible the TVI are caused by radiation
from this cable. I would suggest you to wound 8-10 turns through a
big toroid. The most important thing is permeability to be 1500-2500!

Your cables are secured to the mast by plastic ties. Try to add few
more ties from naked wire - this is a short circuit to radio waves.

I don't see on the roofs TV antennas - it looks you have cable-TV
network (the same is with me). Those cables also may act as antenna.
The only solution is to find some big toroid (diameter big enough to
pass 8-10 turns of TV-cable through it). You should go to your
neighbour, unplug TV cable from TV, pass the cable trough the toroid
few times and connect it back to TV. I did this with two of my
neighbours + my one of my own TV's (hi..hi) and everybody is happy!
Even you can prepare before visit such a filter.
Take a toroid, pass few turns of small coax through it and install
TV connectors (male and female) on both sides. Later you need just
to install this filter between TV and coax cable of your neighbour.

I hope this will help.

2440. Stacked Antennas - HB and VHF/UHF

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-04-28 18:32:29 UTC
From: wv8aa
Topic: 2440 Message: 2440

I haven't found the exact answer in the archives, but I do know that HBs can be stacked. Here's my story; what advice do you have for me? BTW, I haven't spent any money yet, but Dayton is on the horizon:)

In the 80's I had a tri-band yagi and the mast went up through the antenna. So I added a 2-meter vertical at the top of the mast and life was good. Then I moved, took down the tower, beam and all; I actually left the hobby for several years.

So my question is how do I accomplish the same type of stacking with an HB and a multi-band VHF/UHF vertical? None of the pictures I've seen provide an answer. One set of pics did have a pair of HBs stacked with two more HBs on individual arms. The stacked pair looked like the lower one was offset a few inches and the mast went parallel to the central core of the HB.

Thanks for your help and ideas here.

W4RT Electronics will be at Hamvention 2005 in Dayton 20-22 May. The Booth Numbers are 114-115. In addition to having the variety of W4RT products, we will also be the Official LDG Electronics Hamvention Headquarters ... lots of tuners and other goodies plus new items!

There is going to be very interesting special pricing on many items, so come early to the booths in order not to be disappointed because we have sold out of what you want. The pricing is for purchases made at the Hamvention only.

For the first time, W4RT will offer at Dayton DIY kits to install our famous One Board Filter (OBF) in the FT-817, IC-703, and IC-718. The OBF contains a 7-pole 500 Hz and a 10-pole 2300 Hz Collins Mechanical Filter. Now you don't have to decide which filter to install, you can have both! Single Collins Mechanical Filters for the FT-817,FT-857, FT-897, IC-703, and IC-718 will also be available. If you are in the market for these filters, be sure to stop by and check out our filter prices before you buy.

Another new item for Dayton is the MAX PUNCH Module which contains the widely-used W4RT One BIG Punch speech compressor and the highly-acclaimed Heil HC-4 and HC-5 elements. This is a DIY kit for the Yaesu MH-31 microphone that is typically used with such radios the FT-817, FT-857, and FT-897. Want to improve your TALK POWER and bust those pile ups? Then the MAX Punch Module is a great choice!

You can also pick up a bhi, Ltd. DSP module for your FT-817, IC-706, TS-50, etc. at the W4RT Electronics booths. This is arguably the single most important add-on to your radio you can make. This DSP doesn't use the common signal processing methods used by others, but instead employs modern dynamically-adaptive neural-network technology to achieve noise and tone reduction that is remarkably more impressive than other noise reduction technologies available for the FT-817, IC-706, TS-50, and other radios.

See you at the Hamvention!

73,
The W4RT Electronics Team
Barry W4WB

I would like you to let you know one detail..one of the neighbours that just complaint to me, because he is always at the window , he is unemployed.
He said while i had the Hexbeam over my terrace for 10 days,,and i was going upstairs, to change the direction by hand..from North to East .. (it is true), after i had made many calls, on those 10 days withe the hex over the terrace ..no interference.

After 10 when i put the antenna higher 21 meters, all change..
Can it be from the rotary dipole, they are make interaction, puting this TVI???

On those days i did not have :
2) rotor and its cable;
3)Rotary dipole;
4)Remote coax switch.

Can anybody solve this ENIGMA?? Please....

Hi Bill and Company.....

Thank you for your message , wich i do not agree..i wish that was true....the heaxbeam is not RFI free...sorry but is not true..when i had rotary dipole 40..12..17..and 10 i ver interfer in those neigbours, they told last night...now with the hex beam..i am the target from many neighbours,,why????
If it is RFI free you should than tell me....may be mine came with defect..the only i suspect is that she is interacting with the rotary dipole..butnobody knows nothing..even the manufacturer MR.Mike told to me to test and see the results...why is not advertise that this antena is not good for buildings like mine..
Peter Pan and Bamby Story are nice ..but some of your reports, reaally upset me..
Where do you live ...Are you QRP...???
Please do not advertise that Heax beam is RFI..amd TVI free...that is NOT TRUE...
I have been living this nightmeare of RFI and TVI and BCI thought Heax would solve but it make it worst..even with 100 watts i neterfere in many people ..may bee BIll you tell us the miraclefor TVI and BCI and RFI free.

Dreaming is nice ..but this forum is not the best place to..here is to say the reality..but listen i love my heax beam in Performance i do not chnge for any yaggy..i beat the on pile ups easely...so may be this is good to put in a farm..not in town,,where we have aq lot of apartments..
I ask many times MIke about RFI and TVI of Heaxbeam..he did not know ?????
Now if he was an honesty person he should advertise in the technical details: THIS ANTENNA IS VERY SENNSITY AND EASY TO CREATE TVI IN NEIGBOURS.....

I am very dissapointed with MIke atitude..he just don´t care about my problemas of RFI...or he does not know about this subject??????

Paulo, I think you are going to far this time! Mike cannot control your TVI problem. It is very clear from your posting that the whole problem is your neighbors buying cheap TV's with no filtering in them. Neither he nor any other manufacturer can tell you if you will have TVI problems or not. It is all based on what your neighbors buy and how good a radio you use. You have had nothing but complaints about the hex beam since you bought it. Infact people had to go to your QTH to get it working for you which clearly shows you have little understanding of Amateur Radio and Electronics.

Instead of complaining please sell it to a ham that knows how to use it correctly rather than bashing the manufacturer. Failing that move to the country where you will bother nobody. Sorry to be so hard on you but this is getting old.

Hi Paolo,

I think TVI/RFI is not because you use Hexbeam, it may happen with any antenna. Electromagnetic field is so strong near your antenna, so every wire or cable, long enough could act as another antenna and to create RFI.
Please read again my message #2439 in yahoo group from 27 Apr and try what I'm suggesting for TV chocks (traps). Believe me I had the same problem and I solved them by this way. Toroids used are with permeability 2000, dimensions 48 x 28 x 12 mm - big enough to pass few times 7mm TV coax cable through.

Please follow this link http://www.arrl.org/tis/info/HTML/catvi/index.html and look at figure 7.11 and 7.12 to see what I mean.

2450. RE: Hex Beam Help

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-05-19 02:46:13 UTC
From: k9ge
Topic: 2450 Message: 2450

Hi Everbody, sorry about not replying earlier, but I've been laid up for awhile. I want to thank all who replied to my plea for(msg.2419) help with my home brew beam for 17 mtrs. I finally found my problem. in constructing the center post connection points, I had used a long automotive finger type magnet to lower the screws/washers down into the pvc pipe and into the holes (3) I had drilled for the 2 coax connection points and 1 for the screw eye for the center of the reflector. Somehow one of the washers came off of one of the screws and was now magnetized and was making contact between the director and one side of the coax screw. I reasoned that this was why I couldn't get the ant. to resonate above about 17.6 mhz. which was my original problem. I've now have the antenna to resonate at 18.140 mhz. with a swr of 1.5-1 on my mfj 259b, 1.4-1 on my yaesu mk 5 and 1.3-1 on my ys-60, presently I've got the antenna at about 20 ft. It as good as my Dipole at 55 ft. but I expected it to be much better and
am a little disappointed especially the front to back ratio, I realize the tip distances affects this, but I've tried every combination I can think of. I purchased 4 tooth brushes at the dollar store, 2 fluorescent orange and used these for th 5.6" tip spacing of the director and purple colored for the 3.5" tip spacing of the reflector, drilled 3/16 " holes about 1/2" apart for easy adjustment, the orange really helps in seeing the direction the beam is pointing. I've been on 17 everday for about two weeks now and have yet run into anyone running a hex beam. Sure would like to compare notes with someone on the air. I've added 12 mtrs to the beam today, but haven't got it tuned yet. I've been reading about Paulo's TVI problem, I don't agree with all his remarks' but in his defense, I find a very prominent dip at about 55 mhz (about the video carrier for ch.2 55.125 mhz) for whatever that's worth. Again THANKS a bunch for those who sent replys, and Barry it was nice talking to you on the phone. 73's all and Best Regards. Harold - K9ge
PS: I've sent VK2DPD 2 emails with no answers yet, is he still active ? Anyone ?

paulo i agree with mike , if they all have no tvi with there antennas and they all agree and your the only one who disagrees id say what is it when the whole world says yes and you say no , are they right or are you the only one in the world who is right . if your radio , local tvs , and hiuse wireing are cheap then you get what you pay for . in our country they have to put proper filters on the tvs to sell them try to get your country to do this .
fact also , no matter how hard you try and you should try there are gonna be neighbors who will see your antenna and blame you for interfeance the other nighbor haior dryer makes ;-) . and fact is there will be some who you can satisfy and there are gonna be a few who you cant .
the only interfeance free antenna in the world is a dummy load , i suggest you use this ;-) .

From: w4wb
Topic: 2457 Message: 2457

Folks,

It is with sincere regret that I have had to placed Paulo CT2ITZ on a NO POSTING status with this group. This is as close to BANNING as one can get.

The reason is that I monitored a pending message that contained comments about a direct email to Paulo discussing the RFI issues he has and Paulo's reply to the individual. The posting was rejected. Let it suffice to say that the content of Paulo's reply grossly violated the requirement of civility for this group.

Please feel free to attempt to help him resolve whatever problems he may have, but kindly email him directly rather than on this list.

73,
Barry W4WB

2458. Hex Beam Up

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-05-23 15:10:31 UTC
From: mga620000
Topic: 2458 Message: 2458

I just posted a couple of photos of my Hexbeam which I put up after three months. They are in a folder marked WM4N. They are both there if you click on either thumbnail. For some reason, one thumbnail doesn't work for me and the slide show only shows one picture, but they both come up as full size.

I replaced a GAP Titan which stood in the same spot. Only tried a few contacts yesterday evening, but it seems to be working well. The antenna is at about 27 feet. I had to leave the bottom section of the tower off due to interference above.

So far, my reaction is that the HB is pretty good, considering its heighth. I don't believe it is hardly as good as my GAP verticle dipole on DX from my location, but it is quieter. The biggest effect I noticed is that it seems to have much better short range reception. I can hear stations in the Carolinas and Virginia (my QTH is KY) which I could't start to pick up before due to the extremely low launch angle of the Titan. If this trend continues, it looks like it might be a great compromise as a decent DX antenna along with being able to work local.

One thing I found interesting is that it seems to exhibit a lot of directivity but only on certain signals. Most signals in my first test session seemed to be the same through almost the entire beam rotation, while about 10% seemed to be really directional, with the signal falling off rapidly with only 20-30 degrees of rotation. Has anyone experienced this before?

Hi Mate,

My home brew Hex is at 30 feet and has very little front to back ratio but heeps of side rejection. Not sure why.
Does anyone know what may be wrong or are my dimensions out ? Vswr on all bands are under 1.5 !

2460. Hexbeam F/B

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-05-24 18:20:40 UTC
From: dl7io
Topic: 2458 Message: 2460

Hello,
usually we have between 5-15 dB F/B in the model of the antenna. The best F/B is at the lower band edge (CW) where also the gain is best. With a F/B of about 6dB (1S-unit) it will be hard to recognize this on the band. Conditions vary a bit all the time and signal strengths are also changing. To find out the real F/B you need 2 opposite installed antennas and a switch.
I have done this with the 5 band version and found the F/B between 1-4 S-units from the same location and on the same band.
That comes to the question from Harold, K9GE and we also have to take in account the TOA (take off angel) of the antenna. Depending on the antenna height and the (for the skip needed/used) TOA the F/B may be very different again. See also the file I posted a few days ago under Files --> DL7IO.

To come to an example:
If you work on 21.400 with a big TOA of let's say 40-60° you will hardly recognize any F/B
This is one of the compromises you have to make with this antenna.
regards Holger

PS. For the homebrewers I now offer new baseplates made from a thermo-plastic polymere on my webpage (http://www.dl7io.de). This material is UV-resistant, has mechanical features like Aluminum but is easier to handle (drilling etc.).

2461. Field Day 2005

For anyone that may be in the North Alabama area during Field Day June 24-25, you are invited to drop by the Huntsville Amateur Radio Club & North Alabama DX Club Field Day site located on the Intergraph property in Madison, Alabama on I-565. The club call is K4BFT or better known as K 4 Big Fat Turkey. The clubs enter in Class 5A and K4BFT is often #1 in Class 5A and frequently finishing in the top 10 overall.

The 40-m SSB station will feature my 40-30 m Hex-Beam with expectations of helping the club's score more than normal. :-)

If you are in the area, please drop by to take a look at the Hex-Beam and the rest of the antenna farm our groups rapidly erect. It is truly quite a sight and a great example of team work. You are also welcome to operate the stations too!

If you can't visit, then please try to work us!

Tnx es 73,
Barry W4WB

From: RFImages
Topic: 2464 Message: 2464

I was driving through Houten in the Netherlands and I saw this beam. Please click on the 4 photo links below:

http://imagehost.epier.com/30490/DSC03883ant5x7.jpg

http://imagehost.epier.com/30490/DSC03884ant5x7.jpg

http://imagehost.epier.com/30490/DSC03885ant5x7.jpg

http://imagehost.epier.com/30490/DSC03886ant5x7.jpg

This thing is huge and very impressive to say the least.

It was Saturday and no one was at the building to ask about it.

It appears to be commercially built.

Does anyone know what this is?

Thanks,

Bill

I have seen the hex, the spider, and several other designs. I am not sure I have seen this exact one, but there is one similar. It is a log periodic. However, as I look very closely at this one, (I enlarged the photos) I think it could be a log periodic made of delta loops. That's quite an antenna.

That's my guess. I hope you will find the owner and let us know more.

Buck

Will do with the photos. One thing that is an interesting problem is how to mount the HB onto the mast during the erection of the tower. We are erecting 5-6 towers in about two hours with antenna assembly the hour before. Current plan for the Hex-Beam is to take 3 4-foot sections of scaffolding to form a working platform at 12' with the tower pulled up to about 20 degrees. Standing at 12' will make it easy to attach the 40-pound HB to the mast ... we think. With a 50' tower and 3-4' of mast, the interface point is about 16.5'. Other ideas are of course welcome!

AK471
Rotatable Log-Periodic Antenna System

7 MHz to 30 MHz
For transmission and reception of horizontally polarized waves
especially over long distances

The compact Rotatable Log-Periodic Antenna System R&S AK471 is used
for the transmission and reception of horizontally polarized waves.
Due to its transmission frequency range from 7 MHz to 30 MHz it is
used especially over long distances. Reception is possible from 3 MHz
to 30 MHz, leading to coverage of almost all distances. Its low
weight and small size make the antenna system ideal for installation
on roofs.

Special features
Extremely small dimensions
Low weight
Easy and quick assembly
Little maintenance required

or

AK451
Rotatable Log Periodic Antenna System

5 MHz to 30 MHz
For transmission and reception of horizontally polarized waves over
medium to long distances

The compact Rotatable Log-Periodic Antenna System R&S AK451 is used
for the transmission and reception of horizontally polarized waves.
Due to a transmission frequency range from 5 MHz to 30 MHz, the
antenna system is particularly suitable for operation over medium to
long distances despite its extremely small size. Reception is
possible from 2 MHz, thus covering all distances.

Special features
Extremely small dimensions (size of loaded log-periodic antenna for
6.2 MHz to 30 MHz)
Transmission from 5 MHz, reception from 2 MHz
Unrestricted half-wave elements leading to high antenna gain
Easy and quick assembly
Little maintenance required

Dick I don't think that's the one because the data sheet says it is 94 meters long by 88 meters wide and the mast is 66 meters tall. The pictures show this being able to be turned with a heavy duty rotor. I suspect that one unit is the driven element and the other two are directors of some kind. I wish Bill had stopped and asked because Dr. Rhode is a real friend to the amateur community and would have told him. How many people remember the articles that he did for old Ham Radio magazine? If it was still around he probably would have done an article on it. I vaguely remember an article in there at one time about steerable log periodics but don't remember if it was by Dr. Rhode.

Yep.
Its a wire LPDA that uses linear loading for the lower band elements.
I have no idea who made it but it is interesting.

R/S - Rohde and Schwarz makes RF Test Equipment... Service Monitors - Spectrum Analyzers - Base Station / Cell fone test gear. Kinda like H-P / Agilent here in the states. There gear test DC to light. So no uncommon for them to have a wire based log periodic.

Bill,

Looks like a wire log periodic to me. very impressive indeed.

There is a version of this in the ARRL antenna handbook from a few years ago made out of reject pole vaulting poles. This one looks much more sturdy though. Nice pictures.

2481. Re: Field Day 2005

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-06-06 08:02:39 UTC
From: dl7io
Topic: 2461 Message: 2481

Hello Bill,
we had our IARU Region 1 CW-Fieldday last weekend.
I joined some friends at DA0CB/p. One of the antennas was a DL7IO-40-4 (40/30/20/17/15m) @20m height. The other high band antenna was a A3S also at 20m. We tested a bit before the contest and got same reports on 20 & 15m for both antennas.
40m was our best band by DX and No. of Q's. We started in the 100w category with only 1TX but unlimited antennas. I'm not sure how your classes are defined.
I will shortly add some photos to the group or give a link where they are on my website as we are limited with the webspace on the group photo page.
regards Holger

2482. Hex Beam IDEA

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-06-06 20:12:07 UTC
From: mvaughanusm81
Topic: 2482 Message: 2482

Hello all in the Hex Beam group! I have an idea and was wondering if someone would put it to use before field day, (for those who have the resources and time) for this project.

I have been using a "slinky dipole" for the past year in my house. Now for the idea part... What if you used a "slinky" as the director and/or reflector elements for the HEX BEAM antenna? 1)Would the footprint of the antenna be smaller? 2)Would you have a gain comparible to a regular hex beam? 3)What would this do with the spacing for the other bands if you were able to build this?

I know I could come up with the bamboo poles and slinky, but I am in need of the other hardware...i.e. mast, coax necessary for hook up, rotor, to make it work on my own and get back with you.

73's

Mike, WD5CCW

p.s. Thank you Barry for your alertness, your a great moderator!

Hi Mike,

I did stop at the building but it was Saturday and no body was there.
I may be over in that area again in October. If so I will try to
make arrangements in advance to see the antenna up close.

I got a hold of Dr. Rhode's email address and and sent him a note.

Bill

I wish Bill had stopped and asked because Dr. Rhode is a
real friend to the
amateur community and would have told him. How many people
remember the
articles that he did for old Ham Radio magazine? If it was

What really catches my attention is the linear loading for the lower bands. If we could find out more about that we may be able to apply something like that to Hex beams to reduce size on the lower bands. That's why I said I would love to see a schematic of this antenna and it's linear loading method.

Mike

If you look on the photo you see that the company is called Rohde & Schwarz. On the webside www.rohde-schwarz.com you can find the AK451. It is a Log Priodic Antenna for 5 to 30 Mhz. You will find it on top of government buildings and embassys. Don`t think about the price ...

Order me one when you order yours. I'll pay you when I get my paycheck.
;)

I have to admit that it does look quite complex. Being that it is being
sold to governments, I suspect it is very reliable and tough relatively
speaking.

Thanks
Buck

I think I remember a similar antenna design in the ARRL site. It is a log periodic made with wires and string on spacers. It may not be as elaborate, but it will work. A little modification to the design, and who knows, you may duplicate the RF results of the gold antenna.

2494. 3 Elements Hex-beam for 50 MHz ?

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-06-13 20:08:20 UTC
From: Giancarlo
Topic: 2494 Message: 2494

Has anyone experimented on a 3 elements Hex-beam for 50 MHz?
If yes how it was the director integrated and if interlaced with a multiband HF Hex-beam?

I have the intention to assemble a six bands Hex-beam 6m to 20 m.

I do not know if the addition of a 3rd elemnt of such a beam has any sense and worthed gain.

Thanks and 73

From: Dawid Szymański
Topic: 2495 Message: 2495

Hello,

I'd like to invite you to work with station

SN0BSD

that will work from Cracow on 17,18,19 of June
due to MeetBSD 2005 conference (http://2005.meetbsd.org/).

Operators that will handle this:

Lukasz (SQ9JTI), Przemek (SQ8JIV), Dawid(SQ6EMM)

we will work on 80,40,20,10,2 bands (unfortunatelly we have
only 80m dipole on HF bans).

All QSO's will be confirmed with cards.

We will work thanks to help of PROIDEA organization
(http://www.proidea.org.pl/) and ham club SP9PKZ, which
help us to get a callsign.

Details will be on http://hamradio.pl/sn0bsd/

on behalf of SN0BSD
Dawid (SQ6EMM)

2496. A "Hanging Hex"

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-06-22 05:15:50 UTC
From: hopat48
Topic: 2496 Message: 2496

I live on a city lot with several large Oak trees scattered about. Since moving to this QTH about 5 years I have used a 80M horizontal loop draped through the tops of the trees. It worked well enough but I wanted a directional antenna. After reading Mike Traffie's technical articles and various postings here, I decided the Hex Beam was for me but didn't know where I could place it. I hit upon the idea of hanging it from a high limb on one of the Oak trees in the back yard. I ordered a HX5BI from Mike...he said he had never heard of a hanging Hex but that it should work. I found a limb at 40' that looked strong enough to handle the Hex and a small rotator. A sling shot and fishing reel were used to place a rope over the limb. I stood on bathroom scales and pulled on the rope to "load test" the limb. 100 pounds caused about a 2' deflection. 35 pounds only moved it about a foot. I had to cut a couple of interfering limbs to clear the turning radius for the Hex. A "tree limb hook" was fashioned out of 1/4" X 1" strap steel. A swivel mounted pulley was added (rated at 400lbs). I used 3/16" braided Dacron rope to support the Hex. I attachted the rope to a sling using the inner U-Bolts that clamp the element to the hub A second pulley was required near the trunk of the tree to keep the support rope from interfering with rotation of the antenna. The Hex went up the Friday afternoon before the 2005 ARRL DX CW test. I didn't get to operate a lot but sure did enjoy the new "toy". I recently lowered it to move the ferrites to the feed point and to replace the 3/16" rope with 5/16". The 3/16" is rated at 700 lbs but it sure looks small! It's also hard to grip when raising the antenna. I had to us rosin on my glove to control it. I had mounted the ferrites below the hub but noticed the common mode noise from my urban power line environment (BPL would never work these lines...too much interference!) was quite a bit higher on the Hex than my Loop. I don't run the amplifier very often and when I do it's usually at the 500W level. I don't think the ferrites will saturate....and even if they do I don't see a big down side....the pattern isn't that skewed even with no balun. I also added a safety line to keep the antenna from reaching the ground if the rope or limb break. I trenched a 2" PVC conduit to the base of the Oak tree and drove a 8' copper ground rod a few feet away from the trunk. A Polyphaser arrestor is connected to the ground rod. Feeding the antenna with 100' of LMR-400 plus 50' of RG-8.

The Hex performs about like I expected. The 20M element is about 35' above ground. It really makes a difference on weak signals and the nulls off the side really help reduce QRM. All and all I very happy with how things have worked out. I've uploaded three photos that illustrate the lash up!

73,
Pat, W5VY

2497. HEXBEAM DD7ZW

From: Wolfgang Terheggen
Topic: 2497 Message: 2497

Hi all,
Just i uploaded 2 Pictures from my Homemade Hexbeam.
One Picture is the Analyzer Data, the other the Hexbeam on the House.
The Hight is appr. 15m over Ground
The SWR on 12m is about 1:2.8 the other all below 1:2
The 20m Gap between Driver and Reflector is unusual.
I archive in this Position the better SWR.
May this has a effect on the Gain and FB ratio.

Compare to my Moxon i has build before, the FB Ratio less.

73 Wolfgang DD7ZW

2498. Field Day - 40 m Hex-Beam

2500. Re: Field Day - 40 m Hex-Beam

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-06-25 04:43:14 UTC
From: w4wb
Topic: 2498 Message: 2500

Hi Bill,

FB on running the 20 m HB for FD. I had good luck using the 5-band HB two years ago at 55'.

The 40-30 m Hexbeam was setup this afternoon w/o problems. We used a 12' scaffold to stand on while attaching the HB to the mast. We have a portable 30' tower that lifts the towers at the 28' point so that we can then easily set the tower on the base plate. Process takes at least 12 people, but it is safe and quick. The 40 m elements are at about 56'. I put on the SSB elements rather than the CW set since the station is dedicated to phone. The SWR from about 7.150 to 7.3 ranged from about 1.3 to 1.5:1. The SWR rose rapidly, as expected, as the frequency dropped below about 7.150. The 30 m SWR was also just fine. The 30 m elements have to be on the antenna in order for the 40 m elements to perform properly.

Have fun at FB and good luck!

73,
Barry W4WB

2501. Initial Evaluation of the 40-30 m Hexbeam at Field Day

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-06-26 00:52:32 UTC
From: w4wb
Topic: 2501 Message: 2501

After doing some "warm up" on the band just prior to Field Day, I felt ready to have some fun on 40 m SSB. During the warm up time, I did some quick testing with a modest number of hams to get some idea of F/B performance and how they thought my signal compared to others they had heard about the same time. Everyone said the F/B was at least 20 dB and that the signal was very good.

So now the test of fire so to speak began. I ran the first four hours (1800-2200 UTC) and made almost 300 contacts with no duplications (maybe 10 or so called that were dups in addition). This was notably more contacts than the 40 m CW station made during the same period and that is normally never the case. The operating technique I used was to park on a frequency just above 7.225 kHz and call CQ. At one point, my rate was almost 90 contacts per hour. I found it interesting that I could hear a station call off the back of the beam for example that was just slightly covered up by the heavy QRM. I would ask him to QRX for a moment while I turned the beam on him. Signal would notably increase and the contact would be made. Folks seemed impressed with the signal difference. This also helped me fight the QRM. I also note that the INRAD 4 kHz roofing filter I have in the FT-1000MP really is a big help under these band conditions. Also, I am using a G-1000DXS rotor. That fellow really can moved that big HexBeam fast.

Tonight will be interesting when the band opens and the west coast can be worked. Will attempt to provide a wrap-up report on Monday.

If you haven't participated in Field Day, maybe you can get on and give us some contacts! If you are a single operator at home, your report is 1D plus your ARRL Section identifier.

73,
Barry W4WB

Recent test done on 20M with a station in the midwest using a 3 element SteppIR at 70 ft and my HX5Bi at 45ft from California, the signal strength as observed and reported by the station with the SteppIR antenna was 59+ when I beamed toward him. When I turned the HesBeam 180 degree in the opposite direction, signal when down to 53.
We did this three times consecutively and got the same result.
Thought I might share this information with other HexBeam users and all the HexBeam Want To Know out there in radioland.

Duke,

What I've discovered with my HX5-Bi is generally a 20 to 24 dB front-to-back at the lower portion of each band. However, the F-to-B drops as I move up the band.

2504. 40-30 m Hex-Beam Field Day Results

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-06-28 05:45:30 UTC
From: w4wb
Topic: 2504 Message: 2504

Folks,

Seven operators used the 40-30 m Hex-Beam (at 56') at Field Day under the call sign K4BFT (Huntsville, AL) in Class 5A. Everyone agreed that the antenna worked great! We made 865 contacts on 40 m phone.

As I already have reported, a number of stations reported prior to the start of the contest that the antenna demonstrated a F/B of 20-30 dB. In operation under the very heavy QRM conditions on 40 m phone during the contest, this performance was evident.

The G-1000DXA rotor was set to its high-speed setting and really moved the antenna around quickly and nicely. The operators soon learned that this was a tool they could used to enhance the QSO rate. There were many times I could just pick out a partial call sign and would ask the other station to QRX briefly while I turned the beam. Almost always, the station could then be heard Q5!

Sometimes a weak station would be masked a much stronger nearby station from a different heading. In such cases, I often was able to make the QSO by using the deep notch of the Hex-Beam that is about +/- 110 or so degrees from its pointing direction. By rotating the antenna so that the strong station was significantly attenuated, I typically could then make the contact.

The radio I used was a FT-1000MP with an INRAD 4 kHz roofing filter and the entire set of IF filters. There were times I used both the 2.0 kHz IF filters to overcome the very crowded 40 m band QRM.

I also operated from 7.150-7.300 kHz. The MFJ 259B analyzer indicated that the SWR was 2:1 at 7.135, about 1.2:1 at 7.160, and rose to about 1.5:1 at 7.3. Below 7.135, the SWR rose rapidly. The SWR was also fine on 30 m. I did listen on 30 m and noted the F/B was about the same as on 40 m, but I never made any contacts on 30 m since I forget to bring a key ... after all, this was the 40 m phone station.

My only regret is that the antenna is now back in the box until I can erect its new tower.

My sincere thanks go to the many members of the Huntsville Amateur Radio Club (HARC) who made the Field Day activity possible by erecting (and taking down) 5 fifty-foot towers quickly and safely, providing the facilities, and the always appreciated munchies and Saturday night cookout! HARC again demonstrated its capability to rapidly respond to emergencies that may arise, which require amateur radio communications support.

Some folks have asked if the 40-30 m antenna is available from Traffie. The answer is not yet. The one I have is an experimental antenna made up of bits and pieces so to speak. Mike worked on this over a number of months to get it to perform the way both he and I wanted it to do. I am very pleased and certainly recommend it to anyone needing a compact 40-30 m antenna (turning radius is about 19'). I do note that one needs to think about what part of the 40 m band the antenna will be used on mostly. I have a set of elements for the CW portion (my intended portion) and a set for the phone band (Field Day). For general use, I should think the CW elements will serve one well over the entire 7.0-7.3 band if a tuner is used when operating in the phone portion. Of course, the gain and F/B will drop somewhat in the phone band. If you want one of these, you can make one or maybe buy one from Traffie. Contact Mike directly to see if he will make commercial versions. For my part, this new antenna will soon be joining my five-year old 5-band Hex-Beam and the little 6-m Hex-Beam!

73,
Barry W4WB

great report Barry!
And congrats to your contest result. Would have liked to share a report but we are not allowed to radio above 7,1 MHz currently.
This sounds very similiar to my experiences.
I can confirm for my designs that they work from 7,0-7,3 below under 1:2 but of course gain and F/B is best in the lowest working section here CW.
Have you tried to use the antenna on 15m? Depending on the 40m wire dimensions it may work on the whole 15m band as well with gain of about 5-5,5 dBi (free space, no losses).
We made field tests and compared to A3S and FB33 beams (3 element tribanders based on a 15m design) and got same reports/results on both antennas. Antennas where at similiar towers of 20m height and 60m distance in between with same cable/lengths. This was suprising me. And that's why I do not install extra 15m elements into my 40m+ multiband versions.
BR Holger
PS. I can deliver 40m+ versions. Even 3 & 4 band versions are in use since more than 1 year now.

Look in here DL7IO has All the files he has been great at helping all us hams make this great antenna N9IWW
http://groups.yahoo.com/group/hex-beam/files/DL7IO/

look here if do not have the eznec program someone can give you the wire size and lengths you need

down load the file hex beam in 3 hours PDF file it has all measurements in it. Look at DL7IO.de web site he has a lot of information

Thanks again for your help Kevin.
I created a folder (vk2cap) and added the photos
easy and painless if one know how.
I am going to finish the hexbeam
and compare it with my deltas loop
it will be interesting to se witch antennas is the best.

All the best Henning

2511. linear loading

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-06-30 15:48:17 UTC
From: Colin
Topic: 2511 Message: 2511

Hi Guys
I`m pushed for space at my qth and although i`d love a 40m hex it just isn`t practical,I can, however, "just" squeeze in a 30m full size hex.
I`m sure there are others in a similar situation ;)

Has anyone modelled a linear loaded monobander vs a full size?

Ideally the loading would need to be kept to a minimum to preserve efficiency ie: just one band higher perhaps?
so a 30m full size hexbeam would become a linear loaded 40m.

I`m thinking the linear loads could be placed at the element knee points and brought back at right angles towards the center spreaders,which would make an ideal support and give just about enough physical length.

Any thoughts?

2512. RE: [hex-beam] linear loading

Hello Colin,
Take a look at what this fellow did to reduce the size of his antenna. Cheep and easy. I am about to apply the same method to a 40 meter moxon rectangle supported by 4 fiberglass fishing poles, sort of horizontal quad style. It reduces the size by what ever the velocity factor of the coax is you use for the elements. Use regular poly, its .66. Use Foam, is about .81. If size makes the difference, use the .66 stuff. I bought a 500 ft roll on E-Bay cheep several months ago and the method works fine.

From: Colin
Topic: 2511 Message: 2513

Hi Mike
Thanks for the information.
I`ve come across that one before on my travels but haven`t built one from coax.
I did build a regular moxon once but my recollection of the performance was that it didn`t seem to do as well as the hex at this qth.
I`m planning to rebuild the hex, so i figured i`d make the most of it and do some experimenting.
Shrinking the antenna to fit in the space is the goal but if an extra band can be had with reasonable efficiency at the same time, that would be ideal.

I have been thinking along the lines of linear loading somewhat reminiscent of the old 40m force-12 zr vertical, which used a one turn loop at either end of the short center fed 16ft dipole.

http://www.k2kw.com/verticals/image147.jpg

The hex element length would be a much larger percentage of a full halfwave (50%) than this expedition sized antenna and hence less loading would be needed.

Along similar lines is this article which looks more promising:
http://www.wr6wr.com/newSite/articles/features/olderfeatures/antennaswithtwist.html
and also:
http://www.qsl.net/w9anl/newsltrs/2004/0412.htm

If the 20m hex elements stay resonant with an additional spiral coil attached at the ends,reasonable 40m performance might be a possibility from a half sized hex.
(ie: adding 4 spiral coils to resonate the 20m driven/ref elements to 40m)

Whether the spirals would function in the same way as normal end spacings is another question.

Win,lose or draw.. its still fun to experiment.

Hi Rhynhardt,

I suggest you to look also at the Excel sheet:
hexbeamcalcv3 for elements sizes.

I hope you have the space and the support spiders to
assemble an 80 m hex-beam ... spiders will be longer
than 12 meter .... maybe you have nice bamboos there.

2518. Home-brewing a 20-m hex beam

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-07-07 18:59:59 UTC
From: w1cpp
Topic: 2518 Message: 2518

Folks:
I am new to your group. There seems to be a lot of great data here.

I became interested in hex beams when working this last field day and Barry, W4WB, showed his 40-m HB. I did a quick google and found your group.

I am a full-time RVer and need a compact HF antenna for those times when parked. The HB seems just right.

I would like to home-brew a 20-m HB to start and then maybe mod it for 17-m if I succeed. Quick disassembly and reassembly are important to me.

I am searching for reasonably priced fiberglass poles. Any suggestions?

I have down-loaded several of the files you all have produced -- Thanks. However, any advice about got'chas or suggestions are welcome.

73, I am Pete Brake/W1CPP -- QTH: Huntsville, AL till Aug.

2519. Home-brewing a 20-m hex beam spreaders info and how to.

Go to your nearest gander mountain store they have the Shakespeare fishing pole 16'- 20' footers if want that there is a 20 foot but ant present there in short supply you can also make to wire connectors out brass sinks the one that DL7IO has on his web site but the sinks are maybe 2 dollars for 10 ea. You ca use sch 40 electrical conduit 1 1/4" -1 1/2" will work just fine if your not able to make this contact DL7IO he can make you the center feed point if needed, these fishing pole will work great for temp use the collapse inside there self like a Cain pole telescope collapse to 4 foot or less.
You will just need some wire holders made up hold the wire to the spreaders. Look in the files section At DL7IO he has all the measurements you will need also look at the file a hex beam in three hours it will help you a lot.

Subject: [hex-beam] Home-brewing a 20-m hex beam

Folks:
I am new to your group. There seems to be a lot of great data here.

I became interested in hex beams when working this last field day and Barry, W4WB, showed his 40-m HB. I did a quick google and found your group.

I am a full-time RVer and need a compact HF antenna for those times when parked. The HB seems just right.

I would like to home-brew a 20-m HB to start and then maybe mod it for 17-m if I succeed. Quick disassembly and reassembly are important to me.

I am searching for reasonably priced fiberglass poles. Any suggestions?

I have down-loaded several of the files you all have produced -- Thanks. However, any advice about got'chas or suggestions are welcome.

73, I am Pete Brake/W1CPP -- QTH: Huntsville, AL till Aug.

Hello Rynhardt,
before you go for this nice multiband version you should model the antenna. The hexbeamcalc is only usable for monoband versions around 17m. Multiband designs are a bit more difficult and I would not suggest the "trial and error" method.
A 80m monoband design is in the excel file of mine for the calculation of the xyz coordinates for other antenna simulation software (files/DL7IO or http://www.dl7io.de/reflectedw). But untill I have not built a 80m antenna. I'm still looking for somebody who can install this antenna at minimum of 30m height.

2521. Hello all..newbie here

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-07-09 00:50:59 UTC
From: bur52
Topic: 2521 Message: 2521

Hi all.
I am a newbie to this group. I am planning to order a Hex 5 bander. I have spoken to Mike..and it seems to about the perfect antenna for my qth. I do have one question regarding the 5 bande version. Has anyone ever done one with 6 meters added, in lieu of say..12 meters? If that would be a tuning nightmare...How high would I have to stack a mono band 6 meter array over the five bander array?

While I am on a roll...anyone ever do a 6 and 2 meter dual band Hex??? I have a FT-767, and a fl-7000 mp. This rig also has the VHF modules, and I would like to have the ability of all bands on one mast.

I have the typical suburban (non-antenna friendly) QTH. I plan on using heavy duty antenna mast tubing(ten foot sections) Lag bolted to the side oh my House. It will be bracketed and supported by a wall...for about 20 feet of the total forty feet. Then be guyed at the rotor area . If the reports that I have read on this anttenna are true..this looks to be about the best possible set up for me...

thanks

From: ant9845
Topic: 2522 Message: 2522

Hi all.
I have now finished my 20m hexbeam and have it on a 9' pole in the garden between lots of trees.
the reading at 9' is a little high 1: 2.2
It also had a drop test last night in a strong western wind and it survived without any trouble Hi.
My first contact was into the states with good reports.
I did a comparison with my delta loop that is in a much better location the loop was 3db above the hexbeam, I am sure the hexbeam will be better when it get up higher.
Also there is no problem to work 40m using the ft1000 tuner.
Next week it will go up on the mast if the wife will approve, she says old men like me should
not walk around on rooftops Hmmmmmmmm.

2524. 40-80 meter Hex

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-07-10 11:54:02 UTC
From: bur52
Topic: 2524 Message: 2524

Another idea would be interesting. How about a 40 -80 meter single element type. I was thinking of using an alpha delta DXee dipole (40-80 meters) and re-comfiguring it along the lines of the Hex. But it's overall length would be 81 feet(dipole form). It has 40 meters, with two coils for 75-80. What do you think the radiation patterns would be ..if It was (one element) in a configuration such as the Hex? The dipole would be closer to a loop. But it would have the W configuration front and back...same element..

Might make a small package for the space handicaped operator??

Hi Holger

Thank you for the reply. I have been looking at your spread sheet. I also noticed that you biuld the mast for resale? What would a complete beam for 40 and 80 meters cost? I can take a 80 meter beam over 30 meters. We have got a game farm on the Botswna border and we have got biulding taller than 30 meters. And as you should know the propery in Africa is huge. So what did you have in mind with a beam on 80?

Hello all...well I have to say that Mr Traffie is a very unique gent. I spoke to him about three weeks ago. It was in interest in one of his beams. I did in fact want to order one, but he informed me that he was in a back order situation for about three weeks. Since then I had gotten side tracked with some other issues. I called today just to appologize for not following up with him. To my pleasant suprise, not only did He say that the back order was caught up...but he had sent the bean out to me !

Now mind you this may not seem like that big of a deal. But keep in my mind..I have not sent him a payment !! Great guy...and I have to belive that he does have a bond with all fellow hams. If the antenna works half as well as he does things that will be enough for me. But I am sure it will perform even better. Kudo's to Me Traffie and his antennas.

Yes he is! I have a Hexbeam that I purchased used. The antenna was missing some parts and needed some insulators replaced before I could install it. Mike and his son immediately sent them to me and only charged me for the shipping.

The antenna may be expensive but it works extremely well and the customer service is unheard of today.

One of the main reasons for me going with the Hexbeam was this type of service from Mike. The antenna has not let me down and it is really fun to operate QRP with the thing!! It is amazing how this thing works...

I own an Elecraft K2 which has one of the best receivers around. Combine the K2 with the Hexbeam and wow! You got a nice setup.

Greetings Hexbeam group,

I've wanted to aquire a Hexbeam for quite awhile, but unanticipated expenses (car, home repairs, etc.) always seem to pop up and diminish my "Hexbeam fund", so I'm considering trying a homebuilt 17meter version. A local aquaintence has bamboo growing on his property (and owes me a few favors)so I'm about ready to approach him with a request for some bamboo. He has live (green) bamboo and also has a pile of cut, dried poles, and my question is.....which is preferable?.....live green or cut dried? Any advice and/or info will be appreciated. Thanks.

2536. recycle old RG213 coax

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-07-13 14:03:48 UTC
From: Colin
Topic: 2536 Message: 2536

Hi All
In the process of revamping my hexbeam i stumbled over some old rg213 coax in the shed and found a few new uses for it.

Short pieces of the solid dilectric once drilled out with a 2.5mm drill bit make great support tubes for the wire at the knees.

The heavy braided screen can be recycled for the feed connections if you stretch and anchor it to the 20m and 10m element bolts.
Brass washers readily solder to it too.

If you have enough i bet you could use it as heavy duty element wires.

Waste not want not :)

Topic: 2532 Message: 2537

Hi Rich,

I have some home repair that will keep me with my
mouth open for a long time...hi.

The ideal frame support should be done using fishing
poles (sea fishing) 4 or 5 yards type, with 1st or nad
2nd yard rods removed. Cost in Europe (Italy) is
around 10 (<15) US $ per pole. (20 to 10 meters
multiband).

Bamboo was one of the most important antennas support
in the 50-60s.
You should use a well dried bamboo cane. You should
protect it with some paint additive first and then 3
hands of marine transparent flattening. Then you
should be OK ... with an heavier frame.

I expect to assemble my 5 band X-Beam within September
(hope earlier).

Gerry,

I use a TV rotar from Lowes. Its been up 2.5 years with no problems.

Only problem---if using a 3 wire cable get heavy cable, not the typical brand. After a few years it will break. Mine has, so I have to take it down just to replace the wires.

2539. Hexbeam calculations meaning

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-07-14 05:31:00 UTC
From: wb5cxc
Topic: 2539 Message: 2539

This is my first post here, but I have been lurking for over a year.

I'm about to embark on building one of these. I have some questions and didn't want to look through all the posts. On the spreadsheet hexbeamcalc2.xls there is the Driven element/reflective element spacing. Is this the spacing from the end of the element to the spreader? Also the Over All element spacing - I assume that this is the spacing from the end of the driven element to the end of the reflector element (gap between them)?

Am I right or is there something else I didn't or don't understand?

Thanks for the help.

From: Colin
Topic: 2525 Message: 2540

Hi Gerry
According to Mike`s webpage the 5 band hexbeam has less than 5 sq ft windload (0.45 m2) so a 20m monobander would be somewhat lower than that.
It seems a yaesu G450 could manage twice that amount (1m2 or 10.57sq ft) and maybe even handle a 40m monobander at a push.

Regards Colin

Hello all..
Well the hex arrived. I must say it may be pricey..but the antenna kit is first class. Very nicely done ! I never realized the detail that goes into it. Sould last a fairly long time.

I plan on getting it up 30-35 feet...and was pondering a 6 meter mono bander stacked on top. What do you think the spaciing should be, to avoid interaction...6-8 feet?? While I am on a roll, might as well get the magic band handled.

I had my 6M beam 3ft below my 5 band hexbeam. There was no noticeable
interaction except when the 6M beam was mounted at 90deg, then 17M was screwed.

I'm currently building a new 5 band hexbeam and the new antenna will be
mounted in the middle of a pair or 5 ele 6M beams.

John,

From what I understand, it is difficult to put anything directly above the Hexbeam because there is nothing to mount to on top of it. That is the ONLY complaint I would have about this antenna. But I don't stack anything anyway.

If and when I do 6 meters, I will be mounting it to the side of the tower. It definately would be nice to control both antennas with one rotor.

My Hexbeam is about the same height as yours and I have a blast with mine. Let us know when you get the Hexbeam installed and send pictures!!!!

Hi Dave and Group

I'll have some photos of the 20 meter monobander shortly ... it's still sitting at 10 feet ....

As I was saying, this version uses 3/4 inch PVC .... structurally, it doesn't "flop over" at all, although i had that problem with the fiberglas .... they were fishing pole blanks, but they tapered down too much. the reason i scrapped them was that they kept breaking.

on the PVC version, i am using #10 copper conductor, which is also for structural integrity ... there are two nylon tension ropes on the "open faces of the antenna (forward and reverse) ...I have only a slight bow in the PVC's to take the slack out of the conductors and the perimeter tension is maintained by the two tensioning ropes .... it's very sturdy ... the tips don't move at all, although i notices some sway in the middle of the PVC's. I plan to extend a fixed rigid member of some sort (probably off the hub) to about mid-span, and then install another "inner perimeter of nylon cord (used 3/8" all around) to dampen any mid-span oscillation ....

The only issue i am seeing at the moment is that it's pretty heavy and i'm not sure i can turn it with a cheap-o tv antenna rotator from Radio Shack.

It works really well at 10 feet (although it's not supposed to) ... the SWR is 2:1 flat across most of the band ... it noticably directive, even at the test height ....

I must say that most of the ideas for my hex originated right here at the site ... there's been changes but i couldn't have done it without all of y'all 's help ...

Regards to dave and group ... Gerry K2HIG .. near San Antonio, TX

Alice and Dave Billheimer <Trixie@...> wrote:
Gerry, I have questions about your hex. I am working on a new Homebrew Hexbeam webpage and want to include your hex.

I originally used 3/4 inch pvc and had problems. I found that the ten foot lengths of pvc could "twist" very easily and that the hex would sometimes "flop over" so that the curved up ends of the bent pvc would end up not pointing up, but rather would be "lying on their sides" with the bent ends pointed to the side instead. I hope I am making myself clear. Have you had that experience? Have you done anything to avoid it?

What sort of fiberglass poles had you tried?

Can you send any pictures for the webpage?

How did you handle feeding the beam? Is your feedline inside the 2" pvc mast?

I am absolutely fascinated with the hexbeam. Caleb, WA2JJX and I are talking about writing an article for QST. He has worked up a really great cheap homebrew "tower" for his hex that gets it up 22-24 feet and it works well. He mounted his small rotor at the

base of the "tower" and rotates the whole pole. Says it works wonderfully.

Do you know of anyone else who is homebrewing hex beams? I want to include as many people as possible in the new web page.

Trying to assemble a hex beam at home, going pretty much by the outline from the Irish website "Hex beam in three hours" (Try three *weeks*!)

I'm trying the antenna as a monoband 20M, just for starters. (I'm a-mechanical enough as it is, nevermind a five-bander.) Got a hub and spreader assembly done. Spreaders are six ten-foot 3/8-inch fiberglass rods spaced 60 degrees around the hub. Wire dimensions are as such: Driven Element - 36 ft 4.75 inches. Reflector - 36 ft, 10.5 inches. Tip Space DE - 3.1875 inches. Tip Space Refl - 4.625 inches. Base of tip-space triangle - 10.25 inches. Plane of the wires above the hub is 34 inches.

The facets of the hexagon come out to be around 112 (DE side) and 113 (refl. side) . Wires are attached at the very ends of the fiberglass rods. Wires at the facets are reasonably taught. Now here's the problem: the "spoke" wires sag noticeable. That can't be right. What's happening?

I hope this is enough information for a knowledgeable person to diagnose my faults (other than dual left-handedness).

Any and all well-meaning suggestions are appreciated.

It must be that it's summer in the northern hemisphere. A lot of folks seem to be doing this and I have also been planning to build a 20m monobander using PVC electrical conduit for the spreaders. What lengths did you use?

Looking forward to seeing the photos.

My first effort used 1" black PVC electrical conduit, however, a couple of weeks of hot weather and the spreaders started to lose their strength. The spreaders started to bend down before curving up. As a quick fix I slid 3/4" GRP tube down inside the conduit, this gave the antenna the strength back and stopped it drooping.

Hello Mike,
as I understood you have a mechanical problem if the wires sag. Are your spreader to soft?
But nevertheless I have some trouble to understand your writings. What are facets and what is 112 and 113?

Hi Mike
It sounds like the wire from center support to the knee is sagging
but from the knee to the tip (where the gap is)is tight?

Imho it seems the 3/8" doesn`t have enough "spring" to tension the
inner part of the element legs (the spoke wires?).
The dacron (support) lines are tensioning the hex perimeter which is
why the outer legs (facets?)are tight.

Maybe you could add a 5/8 tube (or similar) over the inner part of
the speader, perhaps 3ft or so, to strengthen it?

Regards Colin

i had a similar problem .... i was using a 12 " hub initially, but couldn't get the "spoke" elements tight ...

I did a number of things, including scrapping the fiberglass poles and using pretty hefty PVC (3/4 inch) ..... i went to a 24" plywood hub, which gave me about 11 ft before tensioning ... also using #10 solid copper elements, the PVC has a gentle bend in it and the elements help keep the shape right ... i only have two nylon rope tensioners to keep the outside perimeter tight ..... it seems to be structurally sound, everything is in tension .... but the materials make the thing a bit on the heavy side ...

this is a 20 meter monobander, by the way .... considering adding a 15 meter pair of elements to it, both to gain the additional band and also to better stabilize the center area of the spreaders (but more weight) ....

regards to all ... gerry ... K2HIG .... near San Antonio, TX, USA

Hi John,
the stacking distance between 2 antennas is mostly the
half wave of the band which ist more "high frequently"

In your part means this the stacking size is a minimum
of 3 meter BUT better would be 6 meter.

Enjoy ur Hexbeam and hpe to meet u on 50 MHz.

2558. Re: hex questions

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-07-16 16:00:17 UTC
From: Colin
Topic: 2546 Message: 2558

Hi Stuart,
I guess almost anything can be used for the spreaders.
The main questions are: the cost and how long will it last.

PVC works but above 23C it begins to lose tensile strength and at
140F becomes a soft noodle.
Another drawback is it could take a "set" in hot weather,resulting in
loss of tensile strength.
Painting it white for uv protection is good but bad for stealth,if
you paint it a dark colour it`ll get pretty hot in the sun.

Wood is good and cheap but the weather will warp it given time.

Cheap telescopic fishing rods also good but are very thin walled
(fragile) and will deteriorate rapidly in the sun (coating flakes off)
unless protected.

My own personal choice is white fibreglass tube: (1m) 19mm dia. x
3.2mm wall and (2.5m)12mm dia. x 2.5mm wall.
18 months outside so far and its still as good as new.

On a different note, what about a "no-spreader" hex?
It occurred to me that a mast with 6 non metallic guyes would support
a hex in a fixed direction if you have enough space for the large
base circle.
The slope of the 6 guyes would provide the correct geometry for
fixing the element wires.
A multiband version would be upside down ie: 20m at the bottom and
10m at the top or could perhaps make a good field day 40m or 80m
fixed azimuth antenna.

Regards Colin

Where do you get the white fibreglass tube? and how
much?

Hi Tom
I`m located in the uk so it won`t be of much help to you.
I`d guess you`ll have a lot more suppliers in your part of the world
which helps keep the price competitive.
Over here its hard to find at any price, but I do recall it cost
considerably less than £100 for all of it (including tax and shipping).

Regards Colin

Here in the UK I get my GRP tube from

http://www.sandpiperaerials.co.uk/

Up to 3M long spreaders use their 1/2" tube,

Darren

2563. Re: Frustration

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-07-16 20:53:01 UTC
From: m44austin
Topic: 2547 Message: 2563

Holger,

Sorry about my lack of clarity. That's what I get for writing-while-frustrated.

The numbers 112 and 113 refer to the measurement in inches for the flat sections -- the flats or "facets" -- of the hexagon. This is measured between tips of the spreaders. On the DE side, there is a space of 112 inches between the spreaders; on the REFL side, their is a space of 114 inches between the tips of the spreaders. In my antenna, the wires are attached at the tips of each spreader.

Indeed I do have a mechanical problem. I lack mechanical talent! I do, however, have a speculative diagnosis for my problem. I assumed that the distance from the hub to the "knee" (the tip of the spreaders, in my case) must be equal. If I were to let out some of the hub-to-knee wires and increase the distance between the tips of the spreaders, I can achieve a reasonably taught distribution of wires all around the hexagon. Is it important for SWR, gain or radiation pattern to have equal lengths of wires from hub to knee and from knee to the end of an element?

Regards,
Mike
AA5X

Exactly.

>
> Imho it seems the 3/8" doesn`t have enough "spring" to tension the
> inner part of the element legs (the spoke wires?).

You interpret my jargon very well. Hub-to-knee is the "spoke wires", as I called them. And you may very well be right about the spreaders. Perhaps the 3/8ths rods aren't stiff enough.

However, even with 3/8ths rods, I can get a suitable amount of tension if I make the wire lengths from hub to knee slightly shorter than the wire segment from knee to element tip. This creates less of a bow in the spreader rods, but it does distribute the tension through all the "spoke wires" and "facet wires".

Will doing this have an undesireable effect on gain, radiation pattern or SWR?

> The dacron (support) lines are tensioning the hex perimeter which
> is why the outer legs (facets?)are tight.

Possibly. Like I've tried to describe, I lept to the assumption that all segments of this wires must be roughly equal: hub-to-knee length equals knee-to-element-tip length. In my current configuration, I've got the facets on the driven side at 112 inches from spreader tip to spreader tip. I've got the facets on the driven element side at 113 inches from spreader tip to spreader tip. The sections on each side between the driven element and the reflector are both 112 inches of twine. The more I think about it, the more I'm convincing myself that such emphasis on equal spacing serves no purpose. Is this true?

>
> Maybe you could add a 5/8 tube (or similar) over the inner part of
> the speader, perhaps 3ft or so, to strengthen it?

That's an excellent idea! Once I get the spacing question put to rest, I might do just that, even if only for the extra support.

Regards,
Mike

Gerry,

Thanks for the reply. I'm working on debunking (or confirming) my belief that the "spokes" and "facets" must be pretty much equal and length. When I do this, the "spokes" sag. When I let out the spokes, I get longer "facets" than spokes, but the tension works out reasonably well, even with 3/8ths-inch fiberglass rods.

My hub is assembled from the "wheels" of a wire spool -- plywood circles about 15 inches in diameter. I've cut grooves on each side to secure the rods, strapped down the rods with tie wraps, and secured the two grooved, plywood circles over the rods. After all this, the distance from the center of the hub to the tip of a spreader rod is just over ten feet.

My assembly seems reasonably sound structurally, although I might be inclined to take it down when a hurricane gets a little too close for comfort. The sagging problem is surely the result of my mis-interpretation of something the construction of a hex beam antenna. If the problem isn't in the equal-spacing assumptions, then I'll keep on looking.

Interesting about the #10 solid copper elements!

Regards,
Mike
AA5X

Hi Darren
I checked out the sandpiper site,ideal if they`re local to you and
you only need a small amount.
I recently ordered 6x 5mtr lengths of 12mm od (7.5mm id) and it cost
£78.50 inc the vat and delivery.
They sent it by overnight train/huge lorry in 5.2mtr lengths even
though i asked for 12x 2.5m to make it more compact.

Hi Barry
Although i`ve been around the forum for a good 2 years,
I only recently took the exam and am waiting on a callsign being
allocated by OFCOM,which they say could take upto 4 weeks.

I did the full RAE course at college around 20yrs ago, but didn`t sit
the examination.
By strange coincidence my current instructor (G0RCI - Alan) was on that
very same course.
As soon as i receive the callsign i will certainly add it.
I hope that is ok with you.

Regards Colin

Topic: 2547 Message: 2570

Hello Mike,
the knee element supprts are not at the same distances. They vary a bit. If you put 3 spreaders together to measure you have the knee of the radiator spreader closest to the base plate, than comes the endisolator point and the element leading bush for the reflector element is the most far away positioned one from the baseplate. I suggest to move the hose clamps or whatever you use the way to get the wire not to sag. But please remember there is only one element which is doing a little bit of work in the antenna and this is top element e.g. 20m for a 20-10m version. There are no forces acting in the antenna. Moving this points does not serious infact the features of the antenna. The only critical distances are between 10&12m because they are already so close together.
I hope this helps.
Regards Holger, DL7IO

Mark
Thanks for the kind words.
I`m looking forward to testing the hexbeam on tx (qrp), it`ll make a
nice change from SWL mode.

Regards Colin

From: m44austin
Topic: 2547 Message: 2572

Hi Holger,

Again thanks for the guidance. I'm having a bit of trouble visualizing your recommendations, but that's a result of my failure to adequately describe the problem in the first place. I'll try again.

As you know, the wires form two letter W's: one piece of wire bent at acute angles three times to form a whole "W" (the reflector), while the opposing W consist of two V's joined by the feedline. In my assembly, I've assumed that each straight-line section of a W or a V, the wire length must be equal. In other words, the length of the wire segment from the hub to the "knee" must be the same as distance between spreaders (including the "tip gap). When I do this, the hub-to-knee segment (what I called the "spoke") sags.

Based on your response and others, I'm reading that my assumption is wrong about equal wire lengths. I shall go back to the drawing board, while I continue to invite comment from anyone who cares to contribute.

Enjoy your holidays!

Regards,
Mike

Hi Mike
Do you have a small tube that the wire can run through freely, attached to the spreader at the turning point?

Once you set the tip gap.. the wire should adjust itself by taking or giving up slack via the small tube (driven by the spring of the spreader).
Solid copper wire doesn`t do this very well so flexible wire (flexweave)is probably the best way to go.

Once you have roughly equalised the tension on both parts of the "V", all you have to do then is move the small tube up or down the spreader to ensure the wire is horizontal.

If the wires are the same length and the tip gaps are equal everything else should fall into place automatically

....in theory :)

Thanks John and Barry,
Hopefully i`ll hear you on the bands or perhaps the hexbeam net.
Luckily the hexbeam gives me a good start and a few bands to play on.
I have an LDG AT11-MP tuner so that might provide me with a few more.
A nice compact antenna farm to keep the wife and the neighbours happy.

Regards Colin

2577. Re: Frustration

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-07-18 16:46:02 UTC
From: m44austin
Topic: 2547 Message: 2577

Colin,

To secure the wires to the spreader, I'm using black, UV-resistant cable ties connected to a piece of hose strapped to the ends of the spreaders. The set-up isn't as sound as it could be, but it's cheap, light and relatively easy to assemble (and disassemble). I'm doing mainly this because this is the first time I've built one of these antennas, and I anticipate many tweaks and adjustments ahead. When I settle on a final configuration, I may replace the cable ties with something more substantial.

Thanks to the gracious advice from you and others, I've abandoned the assumption that the lengths of each wire segment (hub-to-knee, etc.) mus be equal. I put a bit of slack in the anchoring cable ties, and the antenna shape and wire tension did indeed sort themselves out quite well, just as you suggested.

I tried for a while to hoist the thing atop a 17-foot stack of PVC pipes, starting at two inches diameter and tapering down to 1 1/4 inch at the antenna hub. I'm unsuccessful in securing it so far, but I'll try again another fine day. By the way, this experience has taught me what it might be like to wrestle a giant spider!

Regards,
Mike

From: on6ec
Topic: 1249 Message: 2578

Hi Group,
Does anyone from the UK uses the Glass Fibre Reinforced Tubes with O.D. 19.0mm (3/4")and 12.7mm I.D. (1/2"), from
http://www.rbjplastics.com/index.htm
I was wondering if this tube will bend a little? If it is too stiff, i can't start off with a slight bend to get the right antenna shape. The plan is to build a 40 - 20 - 17 -(15)mtr Hex starting with a section (1.66mtr) of this size and then go over to 5 mtr long sections of O.D. 12.0mm and I.D. 7.5mm or O.D 12.7mm (1/2") and I.D. 6.35mm
Any experience? Thanks.
Ed ON6EC

Topic: 1249 Message: 2579

Hi Ed
I am using the 12mm (2.25mm wall)instead of 12.7mm, as its a nice
sliding fit,bends well and is still very strong/ rigid.

The 19mm (3.2mm wall) doesn`t bend much, especially in very short
lengths ie: <1m .. its almost like a steel tube of equal wall thickness!

I had to put small wedges underneath it on the mounting plate to raise
the angle for the 10m elements, but for a long 40m spreader i think it
would work very well, from memory a full 5m length of 19mm is quite
flexible.
I do remember that 1.65m lengths of the 19mm and 12mm telescoped
together weigh exactly 0.7kg.
I personally think the 6.35mm would be too flexible.

Regards Colin

Hi all.
I finished the 20m mono Hexbeam last week and it is now on top of a
45ft wind up tower
(see photo in my folder vk2cap)
A thank you to Holger, DL7IO for the good info I found in his folder I
would not have
been able to build this beam without it.
Regards to all Henning vk2cap.

Try Max-Gain Systems who have a large variety of
fiberglass products. They ship via UPS. Used their
rods and tubes to build my hex beam.

2585. RE: [hex-beam] Spreaders from max gain systems tubing sizes From N9IWW

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-07-20 13:26:46 UTC
From: Kevin Adam
Topic: 1249 Message: 2585

These are the Tubing dimensions I used that work out. They are from Max-Gain Systems, but only buy the 8 foot lengths, UPS will be considerable more, but the length and sizes work.
Qty. Size Length
6 3/4" 8 feet Tubing
3 1" 8 feet Tubing
1 1 1/4" 8 feet Tubing
1 1/2" 8 feet Tubing
Cut the 1 1/4" Tubing to make 6 pieces to go on your Hex base plate wirh U-Bolts and add the other sizes accordingly. By the way I used 1 1/4" U-Bolts and had to stretch them a little over a piece of barstock to fit over the Fiberglass Tubing. Only use the 1/2" tubing cut in 6 pieces if you need a little more curve at the end, it isn't necessary, some people like it better.
Wire I used was 14 Gauge Flex Weave 167 strand from Rf Davis, a little pricey but excellent wire for the project.
Band Driven Length Reflector Length End Spacings
20M 219" 222" 5" & 7"
17M 169" 172" 3.5" & 5.5"
15M 145" 148" 3.25" & 4.75"
12M 122" 124" 2.5" & 4.25"
10M 109" 111" 2.25" & 3.5"
These are usually within a couple of inches in being tuned correctly.

Mast Spacing (Approx.) From SO239
20M 1.25" 17M 17.625" 15M 22.625" 12M 27.88" 10M 30.25"
The bottom of the center section is wherever the 10M lines look straight. Go up from the with each to find all band straight rather than the mast spacing dimensions, they are close but may vary a little. Even if they are not straight the antenna still should work OK most of the time. Note the wire dimensions are for one leg side
only, so you will need two of each of these cut. The Aluminum Hex plate I made was 12" and 5/16" thick, but 1/4" and 9.5" across the flats is good also. By the way you tip spacing at the top will be around 113" for 20 Meters wire. Now maybe this will give a few builders better insight. If anyone would like it I can tell you how to do the center pole and Feed connections too. Jerry Farek N5GND

Subject: Re: [hex-beam] Spreaders

Try Max-Gain Systems who have a large variety of
fiberglass products. They ship via UPS. Used their
rods and tubes to build my hex beam.

Thanks for the info, Colin.
While visiting my brother in law, in the UK, next month, I will pay the RBJ-Plastics peoples a visit. It is difficult, to evaluate from a distance, how flexible a tube is. Too stiff and it won't bend properly and too flexible and there isn't enough tension on the wire elements. I Better contact them and inquire if they have the 19mm and 12mm tubes in stock and if they close for the holiday's. And while we are there, maybe secure one end of the tube and lift up the other end to see how much it can bend. One thing is for sure; we won't find these prices here in our region (Belgium, Netherlands, France or Germany), as far as I know.
Also got about 25 pcs of 5 meter fishing rod here but this is useless for 40 mtr.
Regards Ed ON6EC

Topic: 1249 Message: 2588

Hi Ed,
As you said,it is very hard to tell how rigid/flexible this tube is.

I did a quick experiment which may help: using a 1m length of the
tube to lift a 25 litre bucket full of water (25kg?)with the bucket
handle supported in the center of the tube (500mm each side).
19mm tube has hardly any bend... maybe 15mm- 20mm deflection maximum.
12mm tube has perhaps 75mm deflection.
Both tubes can lift the 25kg (25 litre bucket) from the ground
without any problems..very sturdy stuff.

Regards Colin

2589. inverted hex

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-07-21 17:36:11 UTC
From: Eric S. Johansson
Topic: 2589 Message: 2589

I haven't been reading the list too closely by I'm wondering if anyone has considered an inverted hex beam? In theory, one could use a six legged platform for the 20 m section and then using fishing line or rope, create a framework for the remaining four bands. The support ropes would go from the larger six leg framework up to to a smaller six legged framework (10 m?) than one would have 17 to 12 set up in between.

one advantage of this form is that the 20 m platform could be kept relatively straight by to support robes up to the top of the central mast.

yes? No? Must I draw pictures?

All.
I must write and inform eveyone in the group of the excellent service I received from DL7IO. Holger's help in supplying all the information I needed and ready made parts to build a 5 band version of the Hexbeam was excellent. I can highly recommend Holger as a source of parts for this antenna. All parts supplied were of a very high standard, well packed and shipped on time. There are a lot of big dealers that could Learn a thing or two from Holger.

I have to second this.
I have not assembled the antenna yet but work (lack off hi) permitting I will have it up and running this weekend.
The quality of the parts is outstanding and I think I will get a good few years service out of it.

Have Fun

Dick

Ed
I calculated your proposed 40m spreaders (6.5m long?) will weigh
about 1.05kg each and probably cost around 130 euro`s (£90) for the
lot judging by what they charged me, that`s assuming you will have to
pay the vat.
No clue about the shipping cost overseas though.
I guess you could always bring a really big suitcase with you
instead :)

I posted a few pictures on the web showing the spreaders and hub
after 18 months outside.
(The hex is currently stripped and being rebuilt with better hardware)
The lumps on the fibreglass are raindrops by the way.

http://usera.imagecave.com/djcol/Hexbeam/

Apart from some superficial algae growth (which wipes off clean) all
is as solid as the day it went up.

Use quality stainless steel hardware or you can tell by these
pictures what will happen if you don`t!
The hub bolts and hose clamps are stainless but the homebrew u-bolts
aren`t as i couldn`t find any small enough.

The flange fitting (kee-klamp) is made of tough cast aluminium alloy
which should last for years.

Regards Colin

Topic: 1249 Message: 2594

Hi Colin, Thanks for the test. I guess that 5 mtr of 19mm will bend more, but 15 to 20mm for 1mtr length isn't much. And 25 kg is a serious weight. I think it is maybe best to start with a 1.66mtr long section of 19mm (two tubes all together) and then continue with 12mm (6 tubes all together). The 19mm tube is also better to clamp on the hub. Also keeping in mind that one day, the 12mm tubes are more practicle for the 12 and 10mtr band. I see on your pictures that the 12mm fits nicely in the 19mm. The price you mention below, is very competitive. A friend of mine bought a (expensive)5 band fibreglas Quad from a German manufacturer, with the promise that this antenna would last forever. Even the boom was fibreglas. It performed well, but after a few years, the fibreglass started to flake off, due to the UV-ray's. I see it is not the case with your spreaders. But i think to be on the safe side, it is best to paint it with some UV-protective paint, I'm told that the paint they use on the plastic car bumpers will do fine.
We will use the Eurotunnel and put a roof rack on the car. It would be a shame to saw the tubes into pieces. I put them over the roof rack and bend (tie)them towards the front and rear bumper. And yes we also pay VAT in the UK.
Regards.

Ed
I think this stuff is very uv resistant already as it shows no sign of any type of degradation,painting it would help with camoflage as it`s brilliant white in colour.
I have used those cheap fishing poles outside for various antennas and found they do tend to flake after about a year.
I seriously doubt they would pass the same 25kg test.

Your idea of tying the tubes to the bumpers will work great, especially with the 12mm dia.
I measured the tubes i have here and it appears that 5.1m (not 5m)is the standard length.

The price is good and the delivery service I had was excellent.
I sent them a postal order payment as they don`t accept plastic (you may need to make a note of that).

From posting the letter 1st class in the local postbox to the delivery guy banging on the door took almost exactly 48 hours!
140+ miles, full 5.1m lengths for just £14 is very good for uk delivery.

Regards Colin

Hello all

It is put together. It has for the most part very good swr on all bands. A little high on the long end of 10 meters. At 3 feet I worked a few stations with good reports...And feel the swr will improve a little more at normal elevation...

I will try to get it up to 35 feet tomorrow. Should be head and shoulders better than my present fan dipole. See ya on the bands !

Subject: Re: inverted hex

I am not sure I understand your concept, but it would seem you would encounter more disadvantages, namely, its natural tendency to droop, more complicated, expensive and more work than the conventional way in preventing that, and placing your antenna at a lower elevation.
Gerry KC0MSX
---

there are numerous ways to overcome the issue of droop. I was trying to develop a different form of the antenna in an attempt to alleviate many of the problems that make even a homebrew version expensive to build. Expensive that is if you want it to last more than a few months in the sun.

I find the conventional method rather frustrating because none of the documentation people have produced so far describe the mechanical geometry very well. I have only a very rough idea of the curve of a spar, the distance between any two spars for any band, the length of each leg of each antenna element (i.e. distanced from mast to attachment point to final attachment point.

attaching wires to the spars also seems rather crude. There should be a better way of making that work except I really don't know anything about the forces and magnitude of wire/spar movement. there really should be a better way than hose clamps and tubing. For example, for a temporary installation, would it be possible to use Velcro to hold the wires? For more permanent installation, would it be possible to use some sort of low friction plastic screwed or glued to the spar?

now I could reverse engineer this by making some assumptions but these assumptions are just that, assumptions. And yes, I have been through the files and there are some interesting inconsistencies in terms of the spacings between antennas and the length of elements. The only one I remember is the separation between 20 m and 17 m on one of the five band designs was much larger than the spacing described in a spreadsheet of a five band design.

mostly just thinking but I would like to assemble the antenna sitting in my garage someday. Although, given the current sunspot cycle, I may just try a wire 80 m version if I can find a way to get the antenna above 30 odd feet.

Hi Eric
I understand the concept but i do tend to agree with Gerry that the standard configuration is more efficient.
Using 2 sets of spreaders (20m and 10m) will increase the weight by 50% and also the windloading.

I`m sure velcro would be very good for element attachment in portable/temporary situations.
The reason there seems to be a variation of measurements in homebrew hexbeams is likely due to the different spreader materials used.

A really bendy spreader generates a larger vertical spacing between wires because of the large curvature. A much smaller vertical spacing is likely with stiff spreaders which don`t curve so easily.

Interaction (or lack of, in the case of large spacing)would require adjustment to element lengths and/or end spacing.
Type of wire used,location,height and many other variables would also contribute.

This is not to say that you shouldn`t build one as you described.
It should be an interesting project.

Regards Colin

Hi Bill
I`m sure the length does determine the curve to some degree but if you take equal lengths of tube with different diameters they will curve at very different rates.
A recent experiment with a 19mm tube x 1m long took 25kg of weight to create a slight curve. A 12mm tube x 1m long with the same weight curved a lot more as you`d expect.
I`m sure the 19mm could be forced to curve the same but the amount of pull needed to accomplish it would no doubt break the wire holding it or the tube itself :)

I don't think you understand the real reason for the curved arms Colin. For a monobander, it doesn't matter a bit ... even almost straight (not so stable though); however, for a multiband unit it does. You need to have certain vertical separation between the bands so that you can properly attach all of the elements for the different bands onto the same set of arms. If you lay it out, accounting for tip separation and element lengths, you will see that there is an appropriate curve. Oddly enough, it happens to be the arm curve that Traffie uses. ;-)

Hi Barry
I understand the importance of the correct curve for multibanders, but on the homebrew front it can be hard to get the perfect curve (along with the necessary strength and flexibility) using the various homebrew spreader materials.
The vertical spacing between bands on homebrew hexbeams is likely to vary somewhat dependant on the spreader material used.
If the material is too stiff it won`t curve correctly (it could be forced into it but watchout for the whiplash!) and if its too flimsy it`ll curve great but it might not be able to support itself and the wires.These spreaders could even droop below the base plate in the worst case scenario.

Buying a "real" hexbeam is a nice option as all the work is done.
I would certainly consider it, but at £700 ($1240?)its a very expensive proposition here ;)

The Hex as been up only a few days. I have to say, I am like a kid with a new toy!

At 30 feet...worked VK9,multiple Russians, west Africa, Argentina,Norway, Spain, Azores,Finland, England...and a few more. Most were on the first call. Using 500 watts the system seems to be pretty efficient in radiating a good signal. The VK9 was a little tough copy on my end, but he gave me a good signal report. It may be a mini beam...but it works for me. I cannot wait to get it up a little higher !!

What you are describing appears to be a characteristic of the Hexbeam. If you can hear a station (even barely) they appear to hear you much stronger. I've found this to be the case with my HX 5Bi on many occasions and have been told by Mike Traffie that this is quite common. Apparently the antenna radiates very well and has a unique low angle of radiation making it great for DX. Mine is at about 35 feet mounted to a deck. It is my understanding that 35 to 40 feet is optimal for the Hexbeam. I am not sure about yours, but my 5Bi has a flat SWR across every one of the bands. On 20 meters, the highest SWR is 1.5 and the lowest undetectable (1 to 1). It is great to just tune up a station and transmit without worrying about the SWR. I took my AT-1000 Autotuner out of the system immediately and now use it on a ground-mounted vertical on 80 meters.

I am very pleased with the Hexbeam and recommend it to anyone who wants to try and build one or who has the $$$ to buy one. My only advice might be to paint it flat black or gray or some other neutral color to make it blend into the sky and/or surroundings. The white fiberglass arms are quite obvious.

Has anyone played with their 5-bander on the high frequencies?

I have a Traffie five band, and was experiencing some problems with one of my radios. I pulled out the antenna analyzer to do some checking. When I found out it was the radio, I installed a spare mobile rig I keep as a spare. On a whim, I checked the Hex beam on 6 and 2 meters. It looked like it would perform quite well on some useful parts of the band. I hooked up the mobile and sure enough, it transmitted fine, even with its rather sensitive protection circuitry. This was barefoot. With a small mobile tuner, I believe I could work most of both bands. Any one else tried this or had this experience? Having one antenna for 2m through 20m is a really nice proposition.

Hello Charlie,
usually we have center posts of about 4 cm diameter (about 1.5 inch).
If the feeding system is installed inside the center post the elements
have about 1-2 cm air space in between.
I could not notice any serious differences between inside or outside
mounted feeding systems in practice. So I don't think the reason for
the bad F/B will be here.

What kind of wire (diameter/insulation?) are you using. In the model
you can easy calculate versions where the direction will change within
a few 100 kHz. This is because the difference in length between
radiator and reflector is only 1%-4%. But for the radiator the lengths
of the feeding system is still active even if not radiating itself.

So if the reflector is more like a bad director you will have this
impression of no F/B but some side nulls.

Give us please a few more data on element lengths and used material.

Regards Holger, DL7IO

2617. wire for hex-beam

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-08-09 15:26:43 UTC
From: Giancarlo Moda
Topic: 2617 Message: 2617

Hi,

I have the intention to build a 5 bands Hex Beam, 10 to 20 meters including WARCs.

I will use electric wire (multicore) used for electric installations in houses. I have already used this wire for homebrew antennas, including VK2ABQ rectangular shape, and had no problems.
It is not easy to purchase copper wire without pvc protection.

Is here anyone that has used this wire for assembly? I have been calculating a velocity factor of 0.97-0.98. It means the elements will get shorter of 2 to 3%.

Frame will be 6 x 4 meters fishing canes with 1st meter removed.

Subject: [hex-beam] wire for hex-beam

Hi,

I have the intention to build a 5 bands Hex Beam, 10
to 20 meters including WARCs.

I will use electric wire (multicore) used for electric
installations in houses. I have already used this wire
for homebrew antennas, including VK2ABQ rectangular
shape, and had no problems.
It is not easy to purchase copper wire without pvc
protection.

Is here anyone that has used this wire for assembly? I
have been calculating a velocity factor of 0.97-0.98.
It means the elements will get shorter of 2 to 3%.

Frame will be 6 x 4 meters fishing canes with 1st
meter removed.

73

2620. Hexbeam Progress

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-08-13 14:36:36 UTC
From: Colin
Topic: 2620 Message: 2620

Hi All,
I thought i`d to share my experience of my 5 band hexbeam construction as you deserve all the credit for making it possible :)

It`s not completed yet but its getting very close.
I had a few problems getting things level as i live on a hill and my yard slopes in 2 directions,the kids crashing into it every few minutes didn`t help but it is their summer holidays and the hex does take up a fair amount of the space :)

I have posted a few pics showing some of the construction which may be of interest to you.

http://usera.imagecave.com/djcol/Hexbeam/

Hopefully in the next few days (weather permitting) i will check the tuning.
I still have some slack in the wires which needs tweaking a little and then finally i (or the xyl more likely) will decide where to put it and more importantly how to get it there :)

Regards Colin
(M3XBM)

Hi,
Colin's (M3XBM)Hexbeam is looking good! I think the idea of mounting the rotor upside down seems a good solution to the mast/beam intersection. I also noted that the U-bolts seem to be "pre-rusted." I am not so sure that in a moist climate anything but stainless steel will last and it is certainly difficult to disasseble rusted hardware.
Good luck!

Hi Allen
Thanks for the kind words.
The rotator solution was more of a necessity than anything else...i sold my crank up tower a while ago but kept the rotor,which is an older model Emotator.
Being too cheap to pay for a new bottom mast clamp (assuming they still make the) i decided to bolt the hex base plate to the top and move the top clamp to the bottom,the rotator is the right way up :)

The u-bolts are definitely rusty as they were in the air for 18mths,one of those temporary fixes that somehow end up being permanent.
Most of the hardware i`m using now is plastic (less metal in the antenna)
I don`t use hose clamps at the knee`s as I found the small plastic tubes at the knee connections tended to slide sideways when the elements were under tension,effectively pushing the tube out of the cable tie.
The plastic blocks, which use 3.5mm nickel plated brass bolts, solved this problem and were a lot cheaper than stainless hoseclamps.
They probably wouldn`t be very useful for a tapered spreader though ;)

2623. hexbeam update

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-08-14 13:21:40 UTC
From: Colin
Topic: 2623 Message: 2623

Just to confirm the hexbeam needed no tuning as far as swr is concerned.
I hooked the feed to the 20m bolts and ran the coax down the post
between the cold side and reflector,excess coax was coiled to form a
balun.
Every band returned a low swr towards the top of the band with a higher
swr towards the bottom,which is to be expected.
10m swr is higher but also not unexpected.
The hex happily tunes to 40m using the LDG AT11-MP auto tuner.

It may all change for the worse when i raise the antenna (it is at very
low height for now) but i`m extremely pleased with the outcome.

NIce work Colin. As you raise the antenna from a very low height, the resonance freq will rise. For example, with my Hex-Beam at 1-1/2 m, the 20 m resonance was about 100 kHz too low, but when put at operating height, it was then just where I wanted it in the low end of 20 m. 10 m SWR was FB too.

From: Colin
Topic: 2623 Message: 2625

Hi Barry
Thanks for the info, it sounds perfect as the 20m element is only
about 5ft off the ground.
I added 4" of wire to each half element measurement (which is folded
back on itself for now) just in case i needed to extend them.
Heres a quick run down of what i have so far:
14.100: 1.3
14.200: 1.5
14.300: 1.7

18.100: 1.5
18.150 1.4

21.000 1.9
21.100 1.8
21.200 1.7

24.900 1.0
25.000 1.2

28.000 1.2
28.500 2.0
29.000 3.0

It would seem that 10m might need shortening somewhat once it`s
airborne.

2626. 6m results

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-08-14 14:30:32 UTC
From: Colin
Topic: 2626 Message: 2626

I just checked to see what happens on 6m here are those results:
52.000 2.0
52.100 1.9
52.200 1.5
52.300 1.5
52.500 1.0
52.600 1.0
52.700 1.0
52.800 1.2
52.900 1.4
53.000 1.6
53.100 2.0

I wonder if anyone has had similar results?

From: w5ckp@juno.com
Topic: 2627 Message: 2627

Hi Barry, I have built a 20 m. hex beam, with plans to add 4 more bands as I get more confident with my efforts. Two questions;1) Is it important to have taut wires, except for looks, or is the antenna ok performance-wise with non-tight element wires? 2) How much leeway is allowed for tip spacing? I hope to have additional bands operating by friday, depends on weather because SW Louisiana is hot as hell outside. Thanks, David, W5CKP

2628. Re: hex beam questions

From: w4wb
Topic: 2627 Message: 2628

Hi David,

It is best to have the wires taunt. They should also be in the same plane ... driven and reflector. Once you get the wires located correctly, the tip spacing basically takes care of itself. I assume you are following the formulas. All of the elements should lie in a plane for each band and the planes should be parallel to one another.

Good time to get the beam up and working ... P5/KA2HTV should be on 20 m this coming weekend if not before. Dave will be using a 20 m Hex-Beam and have a 700 W amp. Keeping fingers crossed to work the rarest of the rare.

I must admit that I will not be using the Hex-Beam to try to work Dave, but instead some guys and I in the North Alabama DX Club erected a V-Beam on top of a local mountain in a remote area. It has 450' legs, 75' at the apex, 25 deg apex angle, and leg ends are about 35'. For a TOA of 9 degs (highest we can use here according to prediction code), the gain is 13 dBi with a total beam width of 23 degs. This antenna is aimed directly at North Korea. Initial tests demonstrated that it is very quiet.

I understand about the heat down there ... I grew up in Baton Rouge and well remember the 95/95 days.

GL,
Barry W4WB

Yes, nearly identical, SWR about 3:1 at 50.100, however, I had two main lobes +/- 45deg with a null at 0 deg. No real disadvantage for sporadic E since you can park the Hex at 90deg and from the UK and put a reasonable signal into Italy and Scandinavia without having to turn the antenna.

Hi Darren
Its good to compare results,it reassures me i got it right ;)
I finally got the rotor on it today and it stands dominating my
garden at the dizzy height of 11ft to the 20m wire hi.

http://usera.imagecave.com/djcol/Hexbeam/my5BandHexbeamcloseup.jpg

Any lower and i get hooked up in a neighbours fir tree.
10m definitely needs a trim as the elements are very loose and the
swr reflects this, but i`ll wait until i need the band i think.

I just need to make some contacts now..

2631. EZNEC Model of 20-10m 5 band beam

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-08-15 17:02:59 UTC
From: Dave
Topic: 2626 Message: 2631

I just purchased EZNEC and was wondering if anyone had a model for a 5 band, 20-10m hex style beam. I browsed the files section a bit yesterday but couldn't find one for those bands. I figure someone's probably built one already, and didn't want to spend time re-inventing it, so please send me a copy if you can share yours.

Thanks in advance,

- Dave

From: Colin
Topic: 2634 Message: 2634

Well i`ll say it`s working pretty good..
With the hexbeam at just 3.4m (11ft)to the 20m element
WX2F(Lew)in Long Island gave me a nice 58 report..not too bad for just
10 watts!
All you need is a hexbeam :)

From: w4wb
Topic: 2636 Message: 2636

Folks,

It is not looking good for hearing P5/KA2HTV on the air. Dave has to return (last we knew anyway) on the evening of the 23rd. He took quite a bit of equipment with him and had the documents for operating in the DPRK during August.

Primary station is an IC-706MKIIG, ACOM 1010 amp (700 W), W4RT speech compressor, Heil headset, and a 20-m Hex-Beam (provided by Traffie). If he can get on, he should be heard.

He has a backup station comprising an IC-735, W4RT speech compressor, and a 5-band dipole I made for him with a 1:1 balun provided by DX Engineering. The dipole does not need a tuner on 40, 20, 17, 12, and 10 m (SWR is about 1.2:1 to 1.4:1). I selected this approach since 40, 20, and 17 m will be the prime bands for a while. This equipment, plus a MFJ tuner, is planned to be left for future trips or hopefully as the seed for an amateur radio club.

We can hope that Dave still can get on the air during the next couple of days.

73,
Barry W4WB

Hi Barry
Thanks for the info.
I noticed Dave`s call on the dxcluster (maybe yesterday or perhaps the day before) but could not confirm if it was real or not.

Do you have any details regarding specific frequencies Dave might be monitoring if he does manage to put the station together?

It might be useful to get a small headstart on the competition hi

I know that people have used PVC before, But what kind
of PVC? Was it the Schedule 40 Ridged electrical
Conduit? I was thinking of trying that. using 1" ID
with 3/4" id shoved into it for stiffener for the
first bit. Any sugestions?

Thanks,
Tom

Folks,

Our group now has 1300 regular members and about 300 bouncing members for a total of almost 1600!

When this group was started, there were still a number of people wondering if the Hex-Beam really worked, if so how well, and so on. I find it interesting that the question of "if the Hex-Beam really works" has essential evaporated. Over a thousand Hex-Beams, made by Traffie or homemade, are now in use around the world and the user reports are very good.

Experimentation continues and interesting discoveries have been made and shared on this list. I am very pleased to observe the willingness of members to help each other solve problems, share models and data, and answer questions.

Perhaps the "next challenge" is to see who will be the first to build a 60 m or 80 m Hex-Beam. Of course, building it is only a part of the challenge ... you have to have a tower tall enough and be able to install it!

Tnx es 73,

Thats a lot of hexbeams Barry.
I`m amazed that with so many in use i still haven`t got one in the log..I even added a "Hexbeam Equipped" section just in case.
I wonder what happened to the hexbeam net frequencies that used to be displayed on the homepage.
It would be great to work other hexbeam users.

John,

The odd thing about the way Yahoo! handles bouncers is that they often get some mail although hard bouncers get less or none at times. Many of the bouncers actually use the web to view and don't realize they have problems. I used to "fix" the problems, but just leave it alone now.

Colin,

The HB Net sort of died away after a while. Perhaps, there is only so much you can say on the topic. :-) What you might do is to post a notice that you would like to work some other Hex-Beam users and I bet you will get a number of replies. I will be happy to work you after this weekend ... I have to recover my station gear from the P5-Special antenna site. I have worked a lot of Hex-Beam users, both commerical and homebrew. FWIW, Dave's equipment was held for examination by DPRK authorities when he arrived in N. Korea. After a week or so, he was able to meet with the proper authorities, who were very polite and interested in learning about amateur radio. He was allowed to give them a demonstration and they appeared impressed. Regrettably, they were not able to authorize a license for this trip (the documents he received before were approved by a person not authorized to do so ... darn!), but told him that they would favorably consider his application for a P5 license. At least he knows who is the proper authority now, which is no small feat! Why is this important? First, P5 is the rarest of the rare most folks consider. Second, Dave's primary antenna for that activity is a 20-m Hex-Beam specially made by Traffie for compact travel. Now that would have been a great Hex-Beam to Hex-Beam QSO for your log! :-) Oh yes, some of the equipment Dave took was "donated" to the DPRK. It is suppose to be available on the next visit. Interesting.
73,
Barry W4WB

Hi Barry
Sorry to hear that Dave was unsuccessful this time but at least some headway was made for next time.

My hexbeam is still proving itself very effective even at 11ft.
So far i haven`t been accused of used using more than the 10w i`m allowed, but i`m sure some might be thinking it!!
Cuba (4600miles)on 15m (5/9 report)and Morroco on 17m (5/7 report) added to the log last night on a genuine 10 watts output,which was probably closer to 5-7 watts of actual talk power!

Breaking a pile up once its in full flow is almost impossible for me, but if i`m one of the first there it`s very do-able with the hexbeam :)

It`s a pity about the HB net,a list of possible frequencies would be nice as it should increase the chances of working another hexbeam user.
I look forward to working you and others from the group,but not on 10m as i can`t tx on that one yet hi

2647. Hex-to-Hex QSO on 30 Meters

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-08-26 23:20:00 UTC
From: W1GQL
Topic: 2647 Message: 2647

Today I put put a 30 meter Hexbeam and one of my first contacts was Holger DL7IO who was also using a Hexbeam. There can't have been many 30 meter Hex-to-Hex QSOS in the past. I was very pleased, needless to say. My first Hexbeam was built using EZNEC dimensions from Holger's spreadsheet and Holger had recently visited my Homebrew Hexbeam Webpage and made nice comments about it.

My new 30 Meter Hex is continuously loaded (like a "Slinky" antenna) and is the same size as a 20 Meter full size Hex. I will be putting the specs for it on my Homebrew Hexbeam Webpage in the near future.

If you haven't visited the webpage, please do. And sign the Guestbook! The page is at:

http://www.midcoast.com/~w1gql/hex/hexbeam.htm

2649. HEX on 40-10 Meters UK

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-08-28 16:56:17 UTC
From: George Shaw
Topic: 2647 Message: 2649

Folks I am looking ideas and suggestions for a new antenna installation at a new QTH.

Space is NOT a problem as I have 6 acres to play with.

I want to be able to cover with a HEX array the bands 40m through to 10m with main activity on SSB and Data sections of the bands.

What centre frequency will each be cut for? What is the best combination a HX-40-30i to cover 40m 30m and a HX-5Bi to cover 20-17-15-12-10M? What support is required (I was thinking a 2" (50mm) tube support with guys) at what height total and what spacing is required for the combination mentioned? What would be required to rotate this and would it be a case of rotating the hole support pole with the rotator mounted at ground level or rotate each one separate? If separate how would this be mounted? Could the pole support go through the centre of each beam if 2" mounting plates where ordered ? And what effect if any would the aluminium pole have ? What way would the array be connected to the coax if only a single feeder where used?

Sorry for so many questions.

Hi George,
A 40m hexbeam is about 38ft across and would ideally be 60ft (18-20m) above the ground..i`m thinking a 2" pole might not be up to the job.

A 5 band hexbeam doesn`t need so much height(35-40ft) so a 2" mast would fine for that.

The pvc center post of a hexbeam carries the parallel feedlines so it isn`t possible to run the mast through it.
However, you could sidemount the 5 bander below the 40/30 hexbeam though, but interaction with the metal mast is a possibility.

I use a medium duty rotator for a homebrew 5 bander and it doesn`t struggle at all.
A 40m hex beam would likely need something a little heavier duty.

If you are buying the antenna`s direct from Mike you could probably have them cut for whatever part of the band you want.

Just IMHO ;)

DL7IO and others are much better qualified to answer your questions as they operate multiband 40m hexbeams

Hello George & all other readers,
congrats to that property and your possibilities.

I have spent a lot of time with modelling hexagonal beams.
But I have not been able to get more than 5 bands working.

So you will have to go for minimum 2 antennas.

My situation was somehow close to yours. Not 6 acres but close to 1 acre. And my taget was to get all bands from 40-10m rotatable on 1 tower. My decision was a "DL7IO-40-4" for 40/30/20/17m. This one also plays well on 15m with the 40m element. So it is more or less a 5-bander.
For 10/12m I was looking for more than 2 folded elements and had modelled a quad antenna with 2 elements for 15m and 3 for 10&12m (3m boom). Unfortunally ;-) i got a 6 element yagi for 10m (10m boom) for only a few bugs and so this quad project has never been finished. The nice thing with the quad was that the beam would see only small wire dimensions of the quad, naming the top element section.

My first question would be:
What tower is available? My opinion regarding height is a bit different from others. As I'm going mainly for DX I think as high as possible is best. And 18-20m is the minimum for good results on 40m. If you will be loud in Europe make a vertical loop at about 10-15m.

If you have only 1 tower, try to make about 3-4m top mast wich is rotating. Put an antenna for the higher bands close to the top bearing and the 40m beam on top.
You can use a hexagonal beam as well. A bit sidemounted from the mast is no problem for the beam. We have done installations with other antennas mounted above the small hexagonal beam and the rotating mast going through the beam. I have also modelled bigger hf systems below the 40m multiband beams without serious influence. (3 element 20m and/or tennadyne 10 elements logper only 2 m below the DL7IO-40-4).

I now have 4m between the 40m baseplate and the lower beam. My rotating mast coming out of a YAESU 1000GDX is a 60mm DURAL with 5mm thick walls (very strong, under high pressure made aluminum). The distance between top bearing and baseplate of the 40m beam is 4,5 m or 14ft!

We had several force 12 storms meanwhile without any problem for the antenna system.

I have calculated the static as well and the worst case is force 12 wind or more and ice of 3cm radius (means 6cm or 2,36 inch diameter

of the ice!!!). And the point where it would break would be within the steel tower top segment and not in the rotating mast.

Fortunally the wire elements would break first with so much ice, reduce the wind load of the system dramatically and so no serious damage for the tower is expected.

But back to your case. Take a 40m+ hexagonal beam and think about more elements on the higher bands (10/12/15m) if you have space available.
If you can separate the antennas for more than 6-7m you also might think about stacking and go for 2 beams with overlapping bands.

Best Regards
Holger

PS. Dave, W1GQL, nice meeting you on 30. I'm sure this was the first 30m hex-hex contact. Let me please know how you made the beam within the 20m dimensions as I'm still looking for the 80m solution.

When you signed up for Yahoo there was a box that determined if you would receive emails from Yahoo associates. The default is Yes send me emails. You may want to go to your Yahoo settings and see if you can turn it off.

2658. design for 2 hex's needed

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-09-08 16:21:57 UTC
From: Dennis
Topic: 2658 Message: 2658

Hello all,
Looking for a 40/30/20/17 hex and a 15/12/10/6 hex beam. Does anyone have the info on these or have already built these? I hope to mount these on a homebuilt tower about 8ft apart. Mount the high and hex just above the rotator, and the lower hex about 8ft above that. This leaves 2ft of pipe for the rotator and bearings.
Dennis KC9HXE

Hello Dennis,
yes I have built a few of the 40-12m versions. I'm owning 2 myself, one is permanently installed and the other one is used for portable operation. Last weekend it was used by some friends during the IARU region 1 SSB fieldday (DM3W/p).

It is described on my webpage and is called "DL7IO-40-4" if you like to order the complete beam.
regards Holger, DL7IO

2660. Hex beam, Bow tie beam

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-09-11 22:02:03 UTC
From: m1fdz
Topic: 2660 Message: 2660

Hi, I am new to this group, however many years ago when AM was the mode of transmission I worked the world on 100w from an ART-13 transmitter using a 'Bow tie' Beam.
I stumbled across this site today and was amazed to see an antenna loosely based on that old beam of mine, I must admit the 'Bow tie' had amazing performance and was really effective at low altitude much similar to the 'Hex' just a slightly different shape, I was going to build a quad but the QTH here has a few space restrictions so this may be the answer. How does this compare to the Quad and commercial beam antennas? 73 Max M1FDZ

2661. Re: [hex-beam] Hex beam, Bow tie beam

Yahoo group: hex-beam (2001 — 2006)

Topic: 2660 Message: 2661

I used to have a 'Bow tie beam' in the attic of my apartment in 1989, it was made of copper tube and supported by a wooden frame. It was a hexbeam, just called by a different name, the wooden frame made it look different.

I've carried out loads of side by side comparisons between several builds of 5 band hexbeams and other antennae including dipoles, yagis and quads.
It basically boils down to: How much space do you have?, what bands do you operate on?, do you operate CW and SSB? and how much money do you have spare in the bank! If I had the space I'd go for one of those BIG LPY's or try one of those Steppir beams for a multiband antenna.

There are several G's who subscribe to this list and they are there breaking all the pileups with their multiband Hex's, so that's quite a good indication that these antennae work. Obviously not as good as a monoband 3 ele yagi but quite close to a 2 ele.

One last thing, there is a local op near me who has a 4 ele 15M monoband yagi @ 24M high. When we were chatting to W6's earlier in the year both running 100W, I was only 2S units down on his signal. When I increased my power to 250W we were then neck and neck for hours at a time, oh, my hex is 20ft high ;-)

2662. Re: Hex beam, Bow tie beam

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-09-13 01:46:26 UTC
From: Colin
Topic: 2660 Message: 2662

I`m in agreement that for a small space (and bank balance) the 5 band hexbeam is hard to beat.
Big antennas need decent support structures and expensive rotors,not counting the cost of the antenna itself, personally i dont think the cash outlay is worth the gain difference (or the grief from the neighbours)..but i`m not a rich man :)

It is a lot more economical/possible to get a hexbeam to optimum height than most other beams due to weight and windloading.
So it could outperform a 3 ele monoband yagi at a less than ideal height.

Personally, as an M3, i`m very limited in my ability to compete with other stations especially if they`re running even modest power,pileups are a nightmare on 10w!
The hexbeam does allow me the occasional success.
I`m sure with some height and 100w i`ll be able to compete much better.
My best contact,thus far,is Cuba on 17m ..4600 miles, which in my book isn`t too shabby from a homebrew multibander (with 10w at the radio) on an 8ft pole in the garden.

From: Paul van Dam
Topic: 2663 Message: 2663

Max,

Have not used a bow tie antenna, but my understanding of the bow tie antenna is that it is a fan dipole. (A dipole where you have multiple wires to improve on SWR bandwidth (see attached picture)). The hexbeam is a 2 element yagi, where element have been configured as a 'W', for the anatomy of the hexbeam see www.hexbeam.com or pictures at
http://groups.yahoo.com/group/hex-beam/

From: Ken Allen
Topic: 2664 Message: 2664

I'm new to the group. I'm considering adding a 6M HB to my existing antenna stack. I have a TH6 and long beams for 2M & 440. I would like to add the 6M HB to the top of the mast, at 73 ft. This would be about 3 ft above the 2M beam. Would there be any problem with that arrangement? Is the 6M HB sensitive to height above ground like the HX-5Bi is?

Tnx for any opinions,
Ken, KB8KE

I wouldn't bother with a Hex as you obviously have the space there,
you'd be better off with a 3 ele yagi. The yagi would have better gain
and front to back rejection.

Darren

2666. 6 meter height

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-09-23 01:50:04 UTC
From: Mark Oswood
Topic: 2666 Message: 2666

You might also want to think about the optimum height
for a 6 meter beam. Higher is better for line of
sight.

However, if you are thinking about propogation at
longer distances (aurora, E-skip, etc), a 2el 6 meter
beam at 73 feet will result in multiple elevation
lobes with nulls at relatively low take-off angles
(approx 8 and 15 deg.) You can model this with the
HFTA software from the ARRL antenna book. This topic
was also covered in a recent edition of QST in the VHF
column.

2667. SWR

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-09-23 12:40:40 UTC
From: wa2aae
Topic: 2667 Message: 2667

I modified my 5 band Hex (could not get the SWR down on some bands) for 20/17/15M with the dimensions called out in a DL7IO presentation. The SWR on 20 and 17M is pretty flat at 1.5, but the 15M SWR is very high looking better at the high end of the band. Before I lower the antenna to tune 15M, I'm wondering how much I should try to prune the elements (1 or 2 inches?).

The Hex at 15 feet performs equally to my inverted V on top of the house. This is a good indication that when I mount the Hex in its final position at 28 feet it should perform very well.

Thanks.

Harvey, WA2AAE

2668. Re: [hex-beam] SWR

Yahoo group: hex-beam (2001 — 2006)

From: Mike Van Winkle
Topic: 2667 Message: 2668

Harvey,
Pruning would be ill advised. Add wire if its best swr at the high end of the band...Also you can get the amount to add by doing a simple ratio equation of the current resonant frequency divided by the length equals the desired resonant frequency divided by the unknown length...Pretty simple huh...First find out where the antenna is resonantor 1.1 to 1 swr...then measure the actual length...then plug in your numbers and hello ther is the right lenght!...You will also modify the reflector element to 5% more than the driven length...I know some people hate math but this is a lot easier than up and downing that antenna.....Remember to lower resonant frequency an antenna must (at least appear to) be longer not shorter!...Have fun and be careful! 73 Mike KC4JMH

2670. How low can I mount this ?

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-09-23 15:20:13 UTC
From: Ed
Topic: 2670 Message: 2670

I live in an antenna restricted community although I have been successful with installing a Butternut Vertical and a 160-80-40 dipole I would love to have a steerable antenna with gain. This antenna seems to fill some of the goal and appears to be rather small in size. It is not as visible as a Steppir 2 element ! My question is how low can I mount this antenna and still obtain some decent performance ? I doubt that I want to try to go much higher than 20 feet ? Is that too low ? Would it be worth the expense and time ?

Comments most appreciated

Thanks W3ETC Ed

From: Jason Hissong
Topic: 2670 Message: 2671

Ed,

I used it at 9 feet and it worked pretty well! However, getting the antenna up as high as you can get it definately helps. I think a steerable antenna at 20 feet is better than a non steerable antenna at all. You get gain and side and back rejection which is a plus. I think there are guys here that have their Hexbeams mounted on their single story houses. Hopefully they will speak up.

My Hexbeam is at 32' and it really sings. It would probably do somewhat better at 40' to 50', but the extra money and pain to get it up that high was not worth it.

But a Hex at 20 feet should still work ok. It is still better than a dipole up that high!!

Hello
I have a five bander on a 40 foot mast. It is bolted, and bracketed to the rear of my QTH. The brackets are about 3.5 feet apart, and go uo to the 18 foot mark....after that I have it guyed at two level between The beam is swung by a channel master , TV rotor. The controller is a neat little digital unit thatalso has a remote...works great. The antenna is not a a full size tribander , but works very very well for the foot print it uses.And it does not look as menacing to the neighbors. I think that feel it is a large sattelite dish????
good luck

Hi Ed
I think you`ll do fine at 20ft if that`s all the height you can manage.
My hex is on an 8ft pole in the garden for now and it works pretty well
considering.

2674. Re: [hex-beam] SWR

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-09-24 18:34:43 UTC
From: Harvey Mandell
Topic: 2667 Message: 2674

I spent today trying everything 40+ years of HAM radio has taught me. I tried lengthening/shorting the driven and reflector elements, and adjusting the tip spacing. Nothing seems to have any real effect on the 15M swr, it stays around 3:1. 20 and 17M constantly show a good swr. My noise bridge shows that the antenna length is correct, but the impedance presented is very low (around 10 ohms). My MFJ antenna analyzer also shows a very low impedance around 21 MHz also.

The only thing I can think of that I have not done is to change the feedline. Since things work on 20 and 17M I don't see why this should be a problem but who knows.

This whole thing is very strange and any suggestions are appreciated.

Can you describe the method that you are using to feed all the elements
and if you are feeding from the top or the bottom?.

I agree..
I had mine at 25 feet or so. I worked Europe, and Argentina the first time I fired up the rig. At 40 feet is puts out a stronger DX signal...but seems to not quite as strong with stateside stations. Traffie tells me that he has some buyers that have worked dx with the antenna mounted a "bucket"????

Hey,

I spent 4 days trying to get my 15m SWR to play, finally found it to be
the RG213 I was using, I swapped it out and hey presto, all was OK after
a little pruning.

Swap out your coax run with another to see if the problem is still the same.

I'm glad to see that I'm not the only one who has run into this problem on 15m. I'm using about 10ft of RG-58 from the 20M feed point (top feed) with a ferrite balun (current type) between this short feedline and the feedline to the house (RG-8X). I will make up a new short feedline from RG-8X, as short as possible, to replace the RG-58 and hopefully this will resolve my problem. I'm using lengths of 14 GA. wire, held together with tie-wraps, as the transmission line between elements.

Thanks to all.

Hi Harvey,
I used Holger`s measurements for a 5 bander,the only differences were
#14 flexweave and i added 100mm foldback at the end of each half
element (just in case).
I used the same #14 flexweave wire along with the screen from some
RG213 (slid over the top) to create nice thick copper feedlines
around 4mm dia.
Everything tuned with a hitch.
Maybe the reason for your original 5 bander not tuning is still
present in the new 3 band version you have now?
Are you running the coax down the post between the cold driver leg
and reflector?

It`s likely something simple thats causing the problem :)

Hi Colin,

I tried the new RG-8X feedline with no noticeable change in the 15M performance. The feedline is running down the side of the center support between the driven element and reflector connections. My next try will be to disconnect the top feed and try feeding the antenna from the 15M driven element connection. This should prove whether the "transmission line" between elements is the problem. For now I think I need a glass or two of wine to relax. Hi.

FWIW, I'm in the middle of building a 20-15-10 hex and am also having a lot of feed/SWR problems. I tried parallel wires (about 1/2" apart) and couldn't get all 3 bands. If I fed at the top, 10m wasn't good. From the bottom, 20m was bad. Any of the bands fed directly without inter-band connections was fine.

Currently I have it with short coax lines between the 3 sets of wires, and the coax feed going to the 15m band.

Dave,

Why did you use the feed lines 1/2" apart and what king of wire did you use?

For a low impedance feed, which is what the Hex needs, the parallel feed lines should be reasonably heavy gauge, I think mine are multi strand and about 1/4" diameter with a thin PVC covering, these are tied together all the way down and the feed "rings" are soldered on at 90 right angles to the feed lines, this is how I perceive a low impedance feed should be built.

Take a look at the picture in the groups photo files for the coax feed to see the feed lines

Regards,

Jim M0CKE

2686. Re: SWR

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-09-26 14:51:51 UTC
From: Colin
Topic: 2667 Message: 2686

Hi James
I think the wire size is important for the feedline.
I`m not sure about the spacing though as mine aren`t tied closely
together and work fine.

Having said that, my 6mm brass bolt heads are quite close together
inside the 40mm dia post..the 4mm dia uninsulated copper lines are
soldered (aka blowlamp HI) directly down the center line of bolt
heads :)

The thing which stands out for me is the non standard combination of
bands 10/15/20 and 20/17/15 which may be causing the problem.

Initially i`d check and recheck the lengths of the elements.. in case
some are in the wrong place or cut incorrectly.

In Harvey`s case i think the thin #14 wire feedlines are favourite..
thicker wires (4mm) and a return to 5 bands may be the solution.

For Dave, adding 12m and 17m elements could be the easiest way to
go :)
In either case i wish you both the best of luck.

I`m building another 5 bander soon for portable use, so we`ll see if
i`m as fortunate with the tuning as i was with the last one.

I was using #12 solid for the feed, with a harness made with a straight run of wire with ring terminals off it for each band. I picked that because that's what I had on hand. I kept them 1/2 apart since they weren't insulated.

I'll see if I can find some heavy stranded insulated wire and try that with them tied close together. The current setup actually works fine on all 3 bands, however, so I'm working first on getting some frozen bolts out of my used rotor and putting a mast up. I hope to have this going by the California QSO Party this weekend.

I'm on my 4th and hopefully final version here, from my experience you end up with better SWR curves if you use 10mm sq wires zip tied together and the wire elements soldered straight to the feedlines.
On version 3 I made up the two feedlines seperately, I insulated the points where the elements are soldered with self amalgamating tape then zip tied the two lines together.
This gave nice smooth SWR curves on the 5 bands with swr at 1.75:1 (approx) at the bottom of each band.
My MK4 version uses 10mm wire with crimped connections on brass terminals and mounted inside the 50mm centre post, using the same element lengths the SWR curves are all over the place. The problem here is that the feedline widens at the terminals and changes the impedance of the line at this point.

For info, after building version 4 I modded the centre post so the feed studs point to the rear of the antenna. Imagine on a great circle map zero degrees is the front of the antenna, my feed point studs come out at 135 and 225 degrees,this does away with the need for a 90deg angled crimp on the stud. Reversing this post didnt alter the SWR at all.

Incidently heavy duty 2.5mm speaker cable is also about 75-ohms, but is usually quite expensive for long runs, I was toying with the idea of running 75-ohm twin back to the shack to reduce the feeder loses here as the coax runs are about 60M long here.

Well Colin, I tried adding parallel lengths of
insulated braid from RG-8 coax, held together with
tie-wraps, to see if the feedline was the cause of my
problems. Really no difference from the parallel 14AWG
by itself. The weather has turned bad so I can not try
moving the feed point to the 15M element today. At
this point this is the only thing left to try.

Hello Harvey,
sorry for leaving you alone but business comes first and because of
that I have not been here frequently.
I would like to find out what the problem might be but please help me
with some info.
What dimensions for the elements did you use?
Where did you feed the antenna (Top or bottom).
The feeding line is a low impedance line? This means big wire
diameter and wires as close together as you can!

As more distance you have between the wire as higher will be the line
impedance.
Again give me wire diameter (with any unit as I'm not used to #xx
wire), length and details of the feeding system.
I have calculated/published a 20/17/15m beam with feeding at the 15m
element. Is that your base?

2691. The importance of the Feedlines ... !

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-09-27 06:10:32 UTC
From: James Balls
Topic: 2667 Message: 2691

Hi all,

Most who have problems with the home brew beam seem to be overlooking the importance of the low impedance feed lines.

Everyone goes to the trouble of building the beam with correct element lengths and spacings but then compromises on the feed lines and feed coax / choke, these are just as important as the element lengths / spacings.

So you need to make sure you have good heavy gauge cable for the feed lines, if your unsure, then take a look in your local car stereo shop (or ICE shop) for the heavy gauge power cables they sell, maybe you can buy a few meters (or yards) of this type of cable off the roll, it makes for good low impedance feed lines.

Make sure you get the feed take off spacings correct, and once you have made the feed harness make sure the parallel lines are tied together with UV stable cable ties at regular intervals.

On the coax feed, use good quality coax, preferably a new run of RG213 which has been proven to be ok and also that it's not resonant on any of the bands.

Also don't forget the importance of using a coax choke on the feed line just below the base of the Hex, I personally use 8 Amidon FB-77-1024 Ferrite Beads which are held in place with heat shrink to the coax.

All the above works great on my home made hex, I have good SWR curves on all bands and it performs really well, I often get compliments to the strength of my signals running 400w and my PROII, the coax run I use is about 40 Metres (160ft).

I hope this helps those having problems, or just looking to build this fantastic project antenna.

Just remember element dimensions are critical, so are the low impedance feed lines and the coax feed, get them all correct and you will have a performer!

Regards,

Jim M0CKE

Good Morning Holger,

Thanks for your response. The dimensions I'm using came from a presentation I got off of your web site (in German so I hope I picked up the key points); 20M-5.5/5.69M, 17M-4.28/4.41M, and 15M-3.74/3.78M (driven/reflector). The key may be that this version of the antenna was to be fed at the 15M point which I don't believe was mentioned in the presentation, mine is fed at the 20M point. The initial transmission line was 14 GA wire, about 2mm diameter. I then added the coax braid bundled tightly together, about 0.3 inch or 9mm diameter, in parallel with the existing transmission line wire with little or no effect.

I'll try moving the feed point today, weather permitting. I started with the 5 band version, which I also has some problems with, but since I don't operate some of those bands the three band version seemed perfect for me.

Thanks for your efforts and help Holger. Now that I am retired after 39 years in electrical engineering I have more time to play.

One other question Holger. If I want to feed the
20/17/15M Hex from the top (20M point), is it a matter
of only changing the length of the 15M element? 20 and
17 are working fine with the present top feed
configuration.

Thanks again.

Harvey,
the design you used is for bottom feeding as most of the designs I published. I cannot see any advantage for the top feeding. It only causes problems, questions and more coax.
But the radiator should be 4.4m instead of 4.5m.

Yes there is a matter of changing the feeding point.
The low impedance line from the feeding point to the active elements is part of the radiator for every band. It is not radiating itself but has influence on the element lengths. The electrical influence can be seen if you compare the relation between driven element lengths and reflector element length. You will find out that as more far we are from the feeding point as more difference we have (around 1-4% for 20m+ versions and up to 7% for the 40m+designs).

Hopefully everything is working now and you will be able to catch the K7C with your new antenna.

All,

Worked K7C this morning on 20m using the Hex beam 10m and 400w, He heard me after about 5 calls, I couldn't hear him on the 130' doublet or GAP titan but he was 5/5 on the hex with QSB, it still amazes me how low the noise is on the Hex and how well it performs.

Hello to all in this group,

Today I found this group, searching for interesting antenna's to build for the upcoming Jamboree On The Air (14-16 october 2005).
I have never heard before about the hex beam, but it seems a very fun antenna to build and use. Especially with the help of the Scouts it must be fun and good practice to build.
I hope to find enough information in this group to succeed in building this antenna for the Jamboree and maybe more antenna's afterwards.

Kind regards from The Netherlands,
Han.

I recently helped KD5YPF build a monoband 20 meter HexBeam using
information from W1GQL's website. We used PVC pipe for the hex radial
struts and nylon twine for the
remainder of the structure. The hub consisted of 1/2 inch plywood and 1
1/2 inch wood closet rod. This was tried as a prototype for testing with
the idea of using better structural materials if the prototype merited
it. He's had it up for a couple of weeks and is very pleased with its
performance. It's presently mounted at the top of a telescoping metal
mast at approximately 30 feet, appropriately guyed. Today we're supposed
to get winds in the 30-45 mph range. We're thinking it'll survive those
wind levels with no problems, but we'll see. KD5YPF has broken pile-ups
into Sweden with the HexBeam and his normal 100 watt output, which
pleased him immensely. I'm currently seeking locally (hopefully)
obtainable
1/2 inch fiberglass rod to build my own HexBeam. If I can come up with
that material I'll
build one of my own and mast mount it similarly.

Holger,

I was just curious about the element length. Ill stick
to the bottom feed now that everything is working. Now
just have to clean up my work so that I can mount the
antenna in it's permanant location.

Harvey,
good to hear everything is working.
Can you please send me some SWR values (3-4 for every band) together
with info on height and coax length?

I'd be glad to Holger. Right now the antenna is only about 15 feet in the air. I thought that the 15M SWR, which is good at 21MHZ but higher as I go up in frequency would improve as I raised the antenna. It did not so I need to just retune 15M slightly.Do you want the SWR values at this height or do you want to wait until I raise it into a higher location?

Hello.

I have see in your 5 bands 10-20 RefletedW-design, now You feed antenna at bottom.
I have 2 questions:

- Feed is on 10 meter or lower ?
- Lenght of elements is the same as feeding at top ?

Btw: In the past I have try to simulate h.b. with 4nec2 but no result feeding at top, ok feeding at bottom with elements lenght like lz2be model.

Hello Giorgio,
regarding the feeding line:
A high wire diameter is better as the relation between wire diameter
and wire distance gives the impedance of the line and we are looking
for a low impedance line here.

The published 5-band versions are for top feeding.

I have published designs for bottom feeding up to 4 bands (20-12m).
I have a working 5-band solution with bottom feeding and good SWR on 20
as well.

Of course the element dimensions are different from the top feeding
model.
If you have a useful simulation try it out.

2705. Question on height and max mast diameter

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-10-04 08:29:35 UTC
From: f8afc
Topic: 2705 Message: 2705

Dear all,
I was wondering
- how affected can be the results when mounting a 5band hex (HX5bi) at 35 feet only ? (compared to the recommended 45 feet)
- What is the max allowable mast diameter for this beam ? I wish to use a 35 mm diameter mast, but recommendation is 32 mm....
- How can I contact Mr Traffie (or any "customer support" team) for additional questions on this 5 band hex (via e-mail would be my favourite way)?

Thanks for any feedback
Ronan, F8AFC

2706. Re: [hex-beam] Question on height and max mast diameter

From: bur52@aol.com
Topic: 2705 Message: 2706

I have mine at 38 feet.

I works great. Mr Traffie seems to think the sweet spot is about 35-40 feet.
I used a Rohn 50 foot telescoping mast. I discarded the upper most
(thinest) section. And an additional 10 inces of tubing section from the rotor to the
antenna.

I think it was 1.3 inch.

The mast starts out at 2.5 diameter, then gets a little thinner as the
sections go up. I also have it slightly below the max 40 foot height. As I left a
little more length in each section (over-lap), for a little added strenght (I
HOPE). It is guyed at the rotor. And the lower 15-16 feet of the mast is
bolted to the rear of my stucco home.

The antenna works great. I have worked all over Europe, Russia, Greece...and
the Pacific. It may not be a Big beam...but it does put out a decent signal
!!!!
Good luck !

Dear all,

I've carefully looked at the official hex-beam web site and the dedicated Yahoo news group, but I couldn't find any e-mail address where I could ask my question for HX-5Bi antenna...If possibly, I'd like to avoid phoning from France to the States.

Does anyone have Mr Traffie's e-mail address for instance ?

I'd like to get sure of one thing before ordering this HX-5Bi (X-mas season is approaching...What a nice present, HI !)

--> What is the mast diameter accepted by this antenna ? Can a 35 mm diameter mast be OK for this antenna (35 mm = 1.37")
It is said that the mast requirement is 1.325"...

--> I plan to put it at 32 feet high. How degraded will be the performances compared to the recommended 40 feet height..??

Thanks for any answer,
73
Ronan, F8AFC

(Please answer to : ronan.torres@...)

PS : Correct me if I'm wrong, but I think I'll be the first (or at least one of the first) French hams using this Hex-beam...

Mr Traffie does not publish his E-maiil address for the simple
reason that he would not have any time to build antennas if he had to
answer E-mail questions.
I suggest you ask your questions in this forum,,That is what it is
here for.

From: sx88ht20
Topic: 2714 Message: 2714

On Saturday, October 15, BSA Troop 204, Marietta, Georgia, will have 3 hf stations set up participating in the global Scout "Jamboree-on-the-Air". Our callsign will be W4JO, and the station line-up will be:

Station #1 on 20m (+/-14290): Kenwood TS850s / Heathkit SB200 / Hex beam portable

Station #2 on 40m (+/-7270): Yaesu FT897 / W5GI mystery antenna

Station #3 on 17m (+/-18140): Yaesu FT1000d / Buddipole

We will be operating at the Merit Badge University held at Kennesaw State University, Kennesaw, Georgia. We plan to operate from 1300 - 2000 UTC. Over 600 Boy Scouts will be taking one of the 42 Merit Badge classes offered at the event, and we are hoping for a good turnout for the radio Jamboree. Please give us a call and help share the fun of ham radio with the Boy Scouts.

From: Harvey Mandell
Topic: 2667 Message: 2715

Hi Holger,

I retuned the 15M element slightly (shortened about
0.5 inch) to get the 15M swr down. Values on three
bands are: 20M (14 1.0, 14.4 1.2), 17M (18 1.5, 18.2
2.0), 15M (21 1.5, 21.4 1.5). These measurements with
antenna at 15 feet and about a 30 foot feedline.

Thanks again.

From: dl7io
Topic: 2667 Message: 2716

Hello Harvey,
thanks for the data.
In my eyes all bands are a bit to short.
The target is not to have as low SWR as possible.
The SWR curve is going so that it comes down from high values very sharp and moves slighty on a low level before it increases again more softly.
So if you have the situation that at 14.0 MHz the SWR is very low the elements are about 200-300 kHz to short. The SWR in CWportion of the bands should be near 1:2 (about 1:1.8) and comes more down with higher frequeny. This would be better because we would have more gain. Remember that the hexagonal design loses 2 dB gain over the range of about 300 kHz.

If you have a chance, please try to add about 10cm or 4in. to the 20m elements. In theory this should bring the SWR on 14.0 to about 1:1.8 or 1:1.7 and give you the point with best SWR at about 14.3 MHz.

If this works add about 7 cm or 2,8 in. to the 17m elements. This may be a bit to much but it is easier to cut it. 4 cm might be ok here as well.

Where has been the 15m resonance before you cut off the 0.5 in.?

OK Holger,

The SWR on 15M was about 2 across the band and my rig did not like this. To avoid using the antenna tunner I trimmed it so the SWR is 1.5, which does not bother my 751A. When I get a chance I'll try you suggestions to lengthen the elements on 20M. Rain is predicted for the next few days so I'll have to wait to try the change.

Thanks again.

One thing I forgot to question. When I lengthen the elements by 10cm, I assume this applies to both the driven and reflector elements?

Yes Harvey, this is correct.
Add this length to every of the wire elements.

2720. Hex/Dipole A/Bs

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-10-09 17:56:55 UTC
From: Darren GØTSM
Topic: 2720 Message: 2720

Well, I've just completed a week of A/B tests between dipoles for 10-20m against my 5 band hexbeam. Both antennae were using the same length of feeder and the height of the dipole was adjusted to the same height as the hex beam element I was checking against.
The local station I used to check the results with was 9KM away. The last time I ran these tests on a hex made of insulated wire I got a lot of negative results, poor gain negative f/b on 12m etc. This time using Holger's measurements and Flexweave 12# wire the performance is much better.
All measurements are in S units but in reality the S units are about 2dB.

With local station

With DX stations (average sigs)

Hex Gain (S units)

F/B (S units)

Hex Gain (S units)

F/B (S units)

The best performance was on 20M, typically VR2/9M/VK were S9 on the Hex and hardly readable on the dipole due to no signal and loud echoes, this happened time and time again.

When you switch from a dipole to the hex the noise floor dramatically falls away revealing many more stations. I've just worked the 3G DXped on 12M/CW who were 539 on the hex and not even a trace of them on the dipole..
The next experiment is to add a parasitic 10M director to the hex to try and improve the 10M performance.

2722. 30m monobander

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-10-09 15:52:05 UTC
From: zs1vu
Topic: 2722 Message: 2722

Hi Guys,
Anyone got dimensions for a 10.1 mHz mono-bander?
I think the dimensions I found so far were for multi-banders which could possibly be different to a mono.
Thanks,
Johan ZS1VU.

2723. Re: K7C

Good job Jim. I worked K7C on 15 m CW and got him on the 2nd call.
He was 559 to 569 on my 5-band Hex-Beam. I called a friend that
needed KH7K but he wasn't able to hear him at all on his vertical! I
let him listen over the cell phone. Sad part is that he has a 5-band
Hex-Beam sitting in a box in his garage for about a year. He says he
has been too busy to get it up in the air. Oh well.

Hello Johan,
go to the file section --> DL7IO.
There is a file called reflectedWsingleband.zip
This includes EZNEC files and an Excel file with/for singleband
dimensions on the first sheet.

Well, bother, as it were, then!

I made it through to them the easy way. 160 meter CW on 25W to a 40 meter vertical-plus-tuner when they were booming in, first call. I truly did want to work them on other bands, and whilst I did hear them on other bands, it was always at a time when they were focusing on a part of the world other than mine.

My dx-ploits with the Hex beam shall have to wait until the time when a dxpedition is attempting to work my continent at the same time that they are actually propagating to my continent!

When is the next sunspot peak?

Zed

2726. swr 1.2 :1 tune but 3:1 ssb

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-10-15 16:42:38 UTC
From: ke5fqy
Topic: 2726 Message: 2726

I made a homebrew hexbeam.
Very good reception.
it's a 20/15/10.
20 meters without a tuner is 2:1 I can tune it to 1.2:1 using a tuner and RTTY signal at 30-80 watts (ic718). When I switch to ssb to transmit my swr goes real high with my voice. Switch back to a tune tone and the swr is 1.2:1. I just tried CW and the swr seems stay at 1.2:1 (makes sense because it is a tone like the rtty).

Any thoughts.
Thank you

2727. New 20 meter Hex Beam

Yahoo group: hex-beam (2001 — 2006)

Topic: 2727 Message: 2727

Good Evening Hex Beam Friends

I ordered a HXL-20 last week and it arrived today (10/18). Exactly one hour after I opened the package I had completed assembly of the beam. It was on a rollaround cart about 6 feet above the ground. I knew that it wouldn't work at that elevation but I thought it may receive so I ran about 50 feet of RG-58 coax to my IC-706 (100w) in the car. I heard a weak ZS4 on 14,185. I rotated the hex beam by hand and listened for the best received signal. It peaked at about 215 degrees Magnetic (estimated). the ZS4 was now a good 5-7. I called him and immediately received a reply. He gave me a 5-4 report. This is great for an antenna 6 feet high. The VSWR was 2:1 with no ferrite or other RF choke on the feedline.

I have a lot to learn about Hex Beams but I am encouraged to say the least

The difference in SWR readings between RTTY and SSB is most likely a feature of your SWR measurement system. As to the CW versus RTTY, CW is not a tone. CW is pure carrier unless you are using MCW which I seriously doubt.

Another hex on the air !

I worked a number of european stations at 15 feet, the first day I finished mine. I eventualy got it up to 38 feet. Tuesday I worked VQ9OW in the indian ocean. Conditions were so so. But I still managed a 5/8 report, using 500 watts. These antennas are a pretty god set up. It is not a full size yagi...but not a bad choice !
Good luck with it !

Hello All,

Last weekend we had a very good Jamboree with the scouts. I build a five band Hexbeam with the material I could find in the shops.
Not with glassfiber, not available here. But instead I used PVC piping. For those two days of operation it worked very well and I stacked the antenna (very easy to put the parts together again) in the attick for next year.
I found the antenna to be sensitive enough, and I had very noticable front to back ratio. (about 4 S points difference).
The only point of attention might be the the low tension on the wires, due to the PVC it is nog possible to get very straight wires (only if using very thin wire maybe).

For the feedline I used crossed "open-line" with ordinary twinline (in my case loudspeaker cable of 1mm diameter). With normal open line or twinline it is impossible to get the 50 Ohms impedance.
With the crossed line I got a theoretical impedance of about 60 Ohms. Due to the dielectricum it will be a bit lower than that, so very close to 50 Ohm. I have read some threads on the feedline in this group. It is only possible with crossed line to get a low impedance, some of you may want to try this. Another good point of crossed line is less noise in reception (But the piece of line is very short in the HexBeam so the noise is already very low).

At the bottom of the antenna I put an 1:1 balun with coax SO230 connector and a HF choke for the coax.

Height of the antenna only about 6 to 7 meters above ground, in the forest near trees.
We worked Indianapolis, Iceland, Moskou, Cyprus with very good signal reports, between 5 and 9 + with running 75 to 100 Watts.

I know some people made photographs of the antenna, If I can get them I will put them in a map in this group.

Kind regards from Han, PE7AOT

I think I'm going to just cut the 20/15/10m elements for the 5 band version that dl7io describes in reflectedW-design-en.pdf. I've build the antenna once with insulated stranded copper and decided to restring it with bare copper and paying better attention. It wasnt what I had expected and the element length slop cutting and velocity factor made a mess of things. But I would sure like to just do the 20/15/10m elements and skip the rest. Guess if that doesnt work I'll just cut the 17/12 and string them in, worth a shot. I dont see how different the spacing could vastly different, lengths may be.

I cant find anything about just a plan 20/15/10 in the files section, but I cant say its not there, just isnt jumping out at me.

Maybe this will rouse someone on the list, maybe even dl7io will jump up and say "please dont make a monster of my creation!" and tell us what would be better :)

good luck

It seems that you can remove the 12m and 17m elements without
affecting performance, as long as you leave the feedline positions on
the center post at the proper spacing.
Imho,you may as well have all 5 bands though as the cost, weight,
work, and windloading of the additional 12m and 17m elements will be
negligable.

I recently helped a friend build a 20 meter monoband hexbeam. I think his cost for the entire antenna did not much exceed $50. With his HexBeam he has had very similar experiences to what you relate. His output wattage is 100 watts or less. I've been so impressed by his HexBeam experiences that I'm acquiring material now to build one of my own.

After sending the previous message it occurred to me that it might be
useful to other hexBeam antenna homebrewers if I passed on info about
some fiberglass material I've discovered. I've found that in the U. S.
there are several manufacturers of fiberglass electric fence posts.
These are simply rods of fiberglass ranging from 3/8 inch to 1 1/4
inches in diameter and in lengths from 48 inches to 84 inches. Some of
the thicker rods will prove much too heavy for our purposes but the 3/8
inch and 1/2 inch diameters should work well. The makers of these posts
ship to farm and ranch stores all over the country. The sizes available
in your home area will vary according to what the locals choose to sell.
My own southern Oklahoma area seems to be limited to 3/8 inch by 48 inch
posts and I'll have to devise a method of splicing them into the
neccessary lengths. Should the 5 and 6 foot lengths of 3/8 and 1/2 inch
posts be available in your home area creating the neccessary fiberglass
radials should be relatively easy. One could order these lengths of
posts and the prices are relatively low. but there is a catch 22. UPS
and others have premium shipping rates for longer packages (six feet or
longer). I priced some 1/2" diameter 6 footers and the dozen required
came to only about 30 dollars, unfortunately the shipping costs were
about 55 dollars. My Scots blood (and my innate frugality(g)) are
offended by this extortion. There are 2 brands of posts manufactured in

Pennsylvania and at least one other brand made in Minnesota. There may be other manufacturers in addition to these. I envy those of you living close enough to have access to their complete stock. Good Homebrewing, Gents.

2738. elements in the same plane?

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-10-23 18:12:51 UTC
From: buysmart2002
Topic: 2738 Message: 2738

On a multi-band hexbeam, is there any problem if the elements are in the same plane instead of in a bowl shaped configuration? Seems to me it could be easier to construct and get all the elements sized properly if they are all in a flat plane using a rigid structure. Anyone have any ideas as to whether this would work? K4KIO

Close proximetry of the wires will really affect the tuning.
Being in the same "flat" plane will result in all the inner element
legs eminating from the same point.

I did experiment with the flat plane idea by modelling a hexbeam where
all the bands shared a common inner wire to the knee points..needless
to say it wasn`t a great success HI

It`s all fun though :)

Hi

Do you mean a spiderbeam ?
http://groups.yahoo.com/group/spiderbeam/
http://www.spiderbeam.net/
It is much larger than a hexbeam.

I have had my hexbeam since july, still not put it up yet :-)

Its mostly me being able to work on it in 15 minute increments cause of my many other more important things to do like take care of the kids or finish remodeling the bathrrom and put the toilet back in so we can park the car in the garage. I put this thing together last year in time for sweepstakes phone, then took it back down to redo some things that I didnt like how they turned out, still dont like my element attaching to spreader scheme. center hub is too big, spreaders pulled into S shapes... but it seemed to work.

Its that time again to get this thing out and put it up for my yearly contest. I put rings with a paint pen on the spreaders at 20cm intervals to assist with eyeballing things to be sorta all even across the spreaders, have bare copper to redo the elements with, still rethinking how to attach the elements to the spreaders.

So in my 15 minutes at a time existance 8 pieces to cut and put terminal ends on is fairly substantial, especially since as its probably only up for a couple weeks I wont use those bands anyway.

If the leaving off these out works and leaves me the option of putting them in fairly easily later then I'll probably work up those elements eventually and string them. All the mounts on the center mast are there already so it should just be a couple lock nuts and however I attach to the spreaders.

I guess while I'm at it, how are people attaching to spreaders, short of machineing something? I had ss hose clamps with zip ties holding short pieces of tubing, seemed to migrate a bit as it sat there under tension. I've seen essentially the same thing on some of the pics section. dunnno

Thanks

Hi Chris,

I see what you mean :)

The "S" shaped spreaders can be tamed somewhat by adding extra
insulated lines across the non element spans to form complete
hexagons.
You do have to be really careful of the tensioning effect though.

I don`t use any hose clamps at the element connection points, as i
found the tube would be pushed out of the cable tie by the side
pressure of the wire.
A lot depends on what material you are using for the spreaders.

I'm using an 8' length of 3/4" fiberglass tube with a nested 4' piece of 1/2" rod in the end, then a short stub of 1" tube over the 3/4" at the base just to fit the ubolts and be a bit more robust. This was all from max-gain.

What are you using for your connection to the spreaders? I tried just cinching down a small piece of tubing with zip ties which worked ok but everything twisted and looked kinda funny, didnt seem like it was going to work.

I found at one point nylon hose clamps in a zip-tie sorta size, someone was making them in Australia I think, looked like the perfect thing but it was a "will be available soon" type thing and on the wrong continent. Silly internet taunting.

Hi Chris,

Like others i`ve experimented with different methods of attaching the elements to the spreaders.

The main things are that the "clamp" is adjustable on the spreader (for finding the correct placement)and the wire is free to move through it.

Ideally the clamp should be inexpensive,weatherproof and lightweight but still grip the spreader like a limpet :)

Initially the good old hoseclamp and tube approach worked great until the tubes were pushed out of the cable ties,leaving the wires supported by the ties alone..

"Plan B" used plastic blocks is shown in this picture:

http://usera.imagecave.com/djcol/Hexbeam/wireelementsupports.jpg

It worked very well, but unfortunately in high winds the clamps were unable to grip the spreader sufficiently well and slippage occurred,which left the elements somewhat "saggy".

The latest and most successful method is shown in this picture:

http://usera.imagecave.com/djcol/Hexbeam/elementtospreaderconnection.jpg

Initial positioning is achieved using temporary cable ties through the 2 holes.
once found i marked the position on the spreader and drilled 2 holes for the 3.5mm nickel plated brass machine screws.
These are normally used to fix power/lighting sockets to the wall boxes.They come in boxes of 500 and are extremely cheap from any electrical wholesaler (the brass nuts are ordered seperately).

No slippage,no corrosion ,lightweight and very inexpensive.
Also less metal near the elements.
Although i use 3.2mm wall fibreglass tube for my spreaders they do work on the thin "crappie" rods too and are probably safer than tube crushing hose clamps.

With "crappie" rods I would use a single bolt fixing through the "one hole side" and a cable tie through one of the two holes to prevent twist..this leaves a hole for the element wire.
In either case the dacron support lines can also use the holes in the clamps as attachment points.

A dab of exterior silicon sealant over the screw heads and brass nuts
keeps things like new.

Lots of ways to skin a cat as they say, this is the method that has
worked very well for me.

Topic: 2730 Message: 2745

You made those blocks yourself? for a 5 band hex it would be... 30 blocks? a 3 band would be 18... dont think they would be too bad to make, can get plastic stock fairly easily, would guess a drill press and a band saw would be the main equipment needed...

I've pondered something like that several times, just need to take the plunge and get started.

thanks, looks great.

From: Colin
Topic: 2730 Message: 2746

Hi Chris,
I guess you could but it`s a lot easier to buy them :))

They are normally used to fix kitchen worktops to the cabinets
underneath.
They cost about £1.50 for 24 here in the UK.
Your local hardware shop should carry them.

From: chris casey
Topic: 2730 Message: 2747

its a regular thing for me to wander the hardware store with the kids
when we have time to kill, if I walk in there tomorow and have walked
by these things over and over i'm going to be embarrased.

2748. Do anyone trye to make hex-beam for 6 meter band (new on the forum)

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-10-25 14:45:12 UTC
From: Palle A. Andersen
Topic: 2748 Message: 2748

I am new at this forum, so I do not know, if this has bin discussed earlyer.
Do you think a hex-beam would be good at 6 meter-band ??

I have to read for many day to se all the messages here. hehe

I think it would work fine.
But the size of a four element yagi...I would opt for that instead. The Hex is good for me, because of it's small foot print, and five bands.

Hello all

this is a little out of the real of this net.

I am looking for a Swan 500cx..or a 700cx. I am building a Swan station to compliment the Hex beam.
I would prefer a Standard cx model, but will consider a 16 special, for those that know what that is...
thanks, and 73

Hi Colin:
In your description of your (latest)way to attach the elements to
the spreaders, I cannot seem to get your picture to download to show me
what it looks like. I can download the "plan B" picture showing the
white 2 piece pastic on the spreader and it looks good, but
the "latest" picture won't down load for me. Would you please send me
that picture by direct email? amd I'll head to the cabinet store.
Thanks Much - Harold - K9ge

Hi Harold,

I think the problem lies in the length of the link.
If you copy it and add the missing letters "pg" which fall on the next
line it should be ok :)
Here is a clear closeup picture of the "assembly joint" which i used,
they should be available in most countries i guess, but possibly go
under a different name.

http://usera.imagecave.com/djcol/Hexbeam/AssemblyJoint.jpg

Hi Ed

Congrats ! I think it is pretty basic. There is not much to it..other than follow the directions. Make sure that you lone up the marks on the base plate. That will effect the overall lenght of the spreaders.

I had my Hex assebbled in about an hour. Working Dx at 5-6 feet of the ground. It was on a step ladder, as I was checking the swr...I heard a DL station calling CQ on 20 meters. I keyed the mike, and answered....100 watts. He came back to me with a 5x8 report !
They work!

Traffie says that 35-40 feet is about the best height for overall performance. Any higher, it looses the ability to work short to medium skip. Take off angle is low? I am not sure that I understand that...but I have mine at 39 feet, and I have done very well with it.
Last weekend, the world wide dx contest was a good test...many pile ups busted, 600-700 watts 15-17-20 meters. It works...good luck with it.

What are you going to use to get it up in the air? Mast..tower..roof mount??

Congrats on your new purchase. You will find the Hexbeam's performance to be fantastic. Just follow the instructions in the assembly manual, you won't have any problems. Do make an RF choke with 8 turns of coax and tape it just underneath the hub. This will help cutting back on any potentials RFI.
I have mine on a Tri-Ex W51 tower, cranked to about 45ft. I work the world with it and oftenly I have people telling me that I am the loudest station they hear on the band.

Ed,

Major congrats on your new Hexbeam! Be prepared to have a lot of fun
with it. I am looking forward to the SS contest this weekend. I will
be running QRP using the K2 and the Hexbeam. Prop it up 6 or 8 feet and
see how it works for you.

Subject: [hex-beam] New 5Bi

Hi,
I just bought a new 5 bander...should be here by the middle of the week. Any inputs on how to max out its potential before I get to put it up??? any ideas or need to know before I try to get it up this weekend??? any inputs would be greatly appreciated...

Hi,
Thanks for the reply...I have bought a Rohn 40' push up pole to get it up to at least 40'. By the time I do the rotor etc it will be up about 45'...so not to bad...by the way what type of rotor are you using???
I hope to be up no later than sunday depending on wx..we have several fronts going thru.I do have a large garage/shop to maybe put it together depending on how long the spreaders are.
Maybe we can chat on HF then..
73,
Ed NT4TT

bur52@... wrote:
Hi Ed

Congrats ! I think it is pretty basic. There is not much to it..other than follow the directions. Make sure that you lone up the marks on the base plate. That will effect the overall lenght of the spreaders.

I had my Hex assebbled in about an hour. Working Dx at 5-6 feet of the ground. It was on a step ladder, as I was checking the swr...I heard a DL station calling CQ on 20 meters. I keyed the mike, and answered....100 watts. He came back to me with a 5x8 report !
They work!

Traffie says that 35-40 feet is about the best height for overall performance. Any higher, it looses the ability to work short to medium skip. Take off angle is low? I am not sure that I understand that...but I have mine at 39 feet, and I have done very well with it.
Last weekend, the world wide dx contest was a good test...many pile ups busted, 600-700 watts 15-17-20 meters. It works...good luck with it.

What are you going to use to get it up in the air? Mast..tower..roof mount??

Hi,
Thanks fo rthe reply...and the advice. with the choke for clearification...all I do is use coax and do 8 turns and tape it under the hub...it is NOT inline with the coax back to the rig??
maybe I am just thick..sorry.
Hope to catch you on the air this weekend.
Ed NT4TT

Duke - NA1A <na1a@...> wrote:

Congrats on your new purchase. You will find the Hexbeam's performance to be fantastic. Just follow the instructions in the assembly manual, you won't have any problems. Do make an RF choke with 8 turns of coax and tape it just underneath the hub. This will help cutting back on any potentials RFI.
I have mine on a Tri-Ex W51 tower, cranked to about 45ft. I work the world with it and oftenly I have people telling me that I am the loudest station they hear on the band.

6 inch diameter, 6 turns in line...can be put on a piece of pvc pipe...or use the toroides that traffies sells. That is what I did...no TVI issues. Other than in my bedroom. The set is directly under the beam. I have some screen cross hatching, if i run 500 watts or better

Ed,

You will find the RF choke results better if you use ferrite beads.
See the home page for this site for more information. The coax
balun is okay, but not as good ... but do use one of the two in any
case. Have fun. My SN 80/81 has been up for about 5 years and
works great. You might wonder why I have an odd serial number.
Reason is that another chap has SN 81/80. Somehow, some of my parts
when with his antenna package and the converse with my package. No
matter, they both work just fine. hi hi

On the subject of RF chokes,

How would I build an RF Choke for a 40m Hex

Also a choke to cover 40/80/160m ... any ideas?

Jim,

For my 40-30 m Hex-Beam (bottom fed), I use 12 FB-77-1024 beads on the coax just blow the hub. Worked fine for me.

As you go lower in freq, you need more stuff ... beads or coax. Look in the files (see home page too) for info on coax balun.

Well I finally started building mine. I need something for CQ WW CW at the end of the month.

I picked up 10 feet of 6 AWG stranded wire for the feed lines. I am going to use external feed up the side of the wooden closet rod.

Search for DL7IO's web site. He has a lot of information including the feed points. Its all metric but easy to convert.

Hello,
I finished my 2nd Hex Beam. Now 20, 17, 15 and 12m.
This time I used brass tubing, diameter 6mm, for the feeder line between the elements. I soldered the wire elements directly to the brass feeder. Got excellent matching on all 4 bands. I'm feeding from the top, connecting a current balun to the feeding point at the center post. Only slight difference when feeding from the bottom. Had to retune all the elements, of course.
All comments, including DL7IO, are showing the balun below the center hub!
Following this, gave me bad matching on 20m and 17m.
Best 73s
Wolfgang, DL2XC

2786. some questions before I start

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-11-08 15:56:28 UTC
From: Bill
Topic: 2786 Message: 2786

Hello to all

This is my 1st post on this one, I want to clarify a couple of things before I start my antenna

I am going to try and build a 17meter Hex Beam, possilby throw in 12 too. I think I have all the formulas and concepts down,

6180/Freq in Mhz/12 = drv ele in feet

6262 by same reflector in feet

102/Freq driven tip space in inches

65/Freq ref tip space in inches

145/Freq total tip space inches

Now for the elements, I just divide the elements total lengths by 4 and that is the side lengths of the triangles on the elements? Excuse me if I use the wrong terms,

Just what kind of 2 to 1 bandwidth does this antenna have over the bands? Would one have a decent bandwidth on a lower freq like 7mhz?

What's the best way for adjusting the total tip space dead on the money? With the twine on the front and back spreaders or just how is that done best?

Also for a dual band for 12 and 17 can it be feed at a single feed point or is there another matching system required?

Also any tips on the best spreader material and where it can be located would be appreciated

73

Bill W4VD

2787. How much extra wire

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-11-10 18:07:56 UTC
From: n3gnw
Topic: 2787 Message: 2787

Moving forward on the construction. Should have the center feed post done tonight.

Any suggestions on how much longer I should cut the wires for the elements to allow for tuning? I'm thinking three (3) inches (about 7.5 centimeters).

73,
Mark N3GNW

Hi Chris,
For 40 mtr (30-20) you need 6 mtr length for one spreader. The total antenna diameter will be about 12 mtrs.
Regards.

Hi, Edmond-
As I understand it, this is the distance between the end of the (wire) element and the centerline of the antenna (the two spreaders which are between the two "W" shapes of the driven and reflector elements).

If you check page 11 of DL7IO's article there is a good picture showing this...
http://www.dl7io.de/reflectedw/files/reflectedW-design-en.pdf

Hi Edmond,

I personally use 40mm pvc tube for the center post but the brass bolt heads inside the tube are perhaps 20mm (.75") apart on the inside.

Others have gone as low as 12mm (0.5") spacing between ref and driven centers and had good results, so i guess anything in the ballpark would be ok.

2794. My first Hexbeam...

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-11-18 05:09:52 UTC
From: wb8yqj
Topic: 2794 Message: 2794

Hi Guys,

I am replacing my 2 element 15m Moxon (at 30 feet) with the 7 pound monoband version of the Hexbeam from Traffie. The Moxon is mounted on a 3 element Cushcraft 10-3CD frame and yes, both antennas work. It's been a great setup here.

But conditions are in decline and I need to put something for 20 meters atop the push up mast, the Hexbeam is light and won't take up any more space than the old antennas on my single support here in "condoville".

I'm expecting performance similar to a 2 element yagi at the same height. That should really be an improvement over the GAP Eagle here, my current 20m antenna. That one is ground mounted and equivalent to a dipole at 30 feet in my A/B tests.

My question is, how much room do I need to put this thing together, how simple or complicated, and suggestions on a 100 foot run of RG8X as compared to RG8. Running 100watts here. And how critical is a toroid at the feedpoint? Traffie is sending me one of the size that would accomodate RG8X but now I'm waffling on the feed type. ;-)

I am trying to keep the weight to a minimum, because as the push up mast goes up, the guys are loose - I am afraid that one of these times... disaster. The weight of RG8 is a consideration.

At present I have about 11 lbs of aluminum plus an Archer rotor and only a light wood patio lathe to bolt the bottom section to. That's too much, so I'm happy to be reducing that weight.

Any comments at all about the hex in operation or the construction of this Traffie version would be appreciated. I have a box coming on Monday, but very little idea what's inside.

Thanks,
Don Rasmussen WB8YQJ/6

Don,

I've been using the 5 band Hexbeam for going on 5 years now. My config is the beam on a 30 foot push up mast (Traffie's HDX) guyed at 2 levels using 3/16" rope. Rotator at the bottom of the mast about 2" above ground. Rotator turns mast and antenna. I use about 40' or RG8-x to a run of low loss RG-8 on the ground. My take is the weight of RG8 to the beam is far too heavy.

Assembly of the 5 band hex took a couple of hours and as I recall a 15 x 15 work area was adequate. A mono-band hex should be less involved.

I have had no need for torroids or chokes of any kind.

The whole arrangement works fine and quite happy with it.

Hope this helps,

Harry WE1X

2796. home made ugly hex

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-11-19 13:46:25 UTC
From: hambeemer
Topic: 2796 Message: 2796

Figured I had better send a note in regard to my hex. First though thanks to all who throw out their ideas giving Us on the fringes something to work with!
The hex antenna I made is setup for 20, 15, and 6 meters. I have it up on a small pipe tower. Maybe 20 feet up. SWR is flat on 15 and 6. 20 though its 1.2 to 1.4 which is OK with me.
Made it with fiberglass poles, however the length wasn't 10 feet so I had some smaller diameter fiberglass sticks. 3 of these fit nicely within the 1 inch diameter pole. I admit the thing looks wierd with these 3 prongs sticking out on 6 poles. Used stranded house wire #12 and left the white casing intact. The mast is PVC. Used coax ground strap as the connection for the 3 bands. Attached to the pvc with sheetrock screws.
Covered the coax with white liquid rubber.
Next step is to take it down and add a rotor.

take care, antenna work gets done lots quicker when the cold and snow shows up... take it easy if you're working off the ground some.

hambeemer

From: Tom Morris
Topic: 2797 Message: 2797

Hello. I came across some info on the hex-beam antenna online, and am quite interested in building a couple for HF, VHF and UHF operation. (I'd like to start out with monoband hex-beams, possibly making some multiband designs later.) I'm quite impressed with how small these are, thanks to the folded elements!

I found the dimension calculator online, but I'm not really sure which spacing goes where. Are there any diagrams that have this nicely laid out as to how the elements are to be arranged?

2798. Hexbeam... Cut the coax?

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-11-23 05:41:30 UTC
From: wb8yqj
Topic: 2794 Message: 2798

Hi Guys,

The Hexbeam HXL-20 project starts tomorrow. Hurray! But I have a decision to make.

I have 100 feet of RG8X with silver connectors on each end. Traffie sent me a Type 77 toroid that's supposed to take 3 loops at 5 inch diameter.

I have to cut the coax and solder a connector to make that work. I don't have a butane torch and trust the factory fittings but have, in the past, put the big Weller 140 Watt gun to work.

Can anyone suggest the practical aspects of having or not having that coaxial balun in the line for the 20 meter monobander?

Any effects on forward gain, front to back, or otherwise at 100 watts?

Thanks in advance,
Don Rasmussen
Carlsbad, Ca.

If anyone needs snap-on toroids to make balun for the HexBeam (or anything else), I got about 500 of these available. They fit perfectly over the RG-8 or 9913 size coax. I also have several thousand of the smaller snap on toroids that fit over the RG-59 or standard TV coax cable. These toroids work fantastic in suppressing RFI. I use both extensively here at my shack and RFI proof.

From: wb8yqj
Topic: 2801 Message: 2801

Hi Guys,

I build my antennas with very few exceptions.

I took a chance about 5 years back and paid $400 for a Mosely mini tribander that is now rusting on the ground in my back yard.

But this HXL-20 is just like a vacation, that's the only way I can put it. Been a ham for 30 years and never had a 20m gain antenna for size and tower reasons.

This antenna "snaps" together and is light enough to carry up a ladder over your head with one hand - which is what I did. Put it on a push up mast, no problem.

I put mine at 35 feet and it acts like a true yagi - a strong performer.

I'll be spending some time in the hamshack this Thanksgiving. ;-)

I did split the coax, installed the ferrite, and found a trick I like for the PL-259 and reducer on the internet. Just use some fine sandpaper from the front of the reducer back to the threads and tin lightly with your Weller gun or high watt iron. Slip the coax in, fold the braid over, and heat it until it wicks up the solder underneath in 4 or 5 spots. Screw on the PL-259 (you may need to cut or file away some braid) then fill the solder holes (quickly). Solder the center conductor as usual.

Worked like a charm here, good braid contact without subjecting the entire connector to loads of heat.

Put the ferrites on the coax. The purpose is to mitigate common-
mode current on the exterior of the coax shield.

From: n3gnw
Topic: 2804 Message: 2804

I've been quiet here (and just about everywhere else on the net) since I said I was building a 5 bander.

I got it together last Sunday (about 36 hours total work) but it didn't load on any band. Checking with an ohmmeter showed a dead short in the parallel feed line. I was going crazy trying to figure out where the problem was and not having any daylight after work. Finally my neighbor wondered if the screweyes I used could be shorting together in the mast. And that was it.

Once I unshorted them and fired it up, it loaded nicely on 20 - 15. I adjusted 20 and it is now flat across the band as is 17. 15's SWR is a little high at the top end of the band. 12 is resonent out of band and 10 is narrow but that could be due to the metal frame of the picnic table its on.

I'll try to finish tweaking it this evening and get it up on a 20 foot mast tomorrow for the contest this weekend. Hopefully, I'll find the digital camara and get some pictures.

This has been built as a temporary antenna with PVC electrical conduit as spreaders and a prototype but if it plays out I'm definitely looking at a official Traffie version. The PVC does take on some interesting shapes.

Thanks to everyone for there info and pictures of their antennas. This is the most major thing I have built from the ground up in ham radio.

73,
Mark N3GNW

Hello Mark,
congrats on this.
It is not the easiest project to start with.
Is the top end the CW portion around 21.000 kHz?
Than the wires are probably a bit to short.

Hope to catch you in the test.
We will be DP9A (multi/multi).
I will be running 40m with 2 x 2 element beams at 2 towers in 20m &
17m height. One is a hex and the other a 2 element yagi.
The high bands have beams with a few more elements.

73 Holger, DL7IO

Hi Barry,
Not sure of the exact mix nature, but they work extremely good for RFI suppressing. I believe they are mix 77. I use them here in the shack and out on the feedline to the antenna, use them on stereo speaker, telephone, alarm systems, you name it. It knocked all the RFI dead. I can run full legal limit now without any RFI situation.
I can send some pictures of them if you're interested.

Hey Mark,
Same here.. hehe. Learn more from others asking than if I send out a plea! The Hex I made is 20,15 and 6 meters. 15 and 6 the SWR is flat across the bands. Cool! Had some troubles with 20. And someday I would like to find the MFJ 259 so climbing a ladder would be less! I did get the SWR to drop to 1.2 to 1.4 on 20.
Neat antenna though. Even the neighbor is impressed! Wanted to know if I could hear airplanes...

2809. Re: Toroids

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-11-25 17:34:41 UTC
From: w4wb
Topic: 2806 Message: 2809

Hi Duke,

Thanks. I have not seen split Type 77 beads offered, just the Type 43. 43 can work to some degree, but not nearly as well as 77 particularly on 20 and 17 m (not to mention 40 m). Pse do drop me a photo if not much trouble.

73,
Barry W4WB

2810. Re: SWR

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-11-26 14:22:31 UTC
From: Harvey Mandell
Topic: 2667 Message: 2810

Holger,
While you were in New York I had sent you an email questioning how lengthinging the elements would raise the resonant frequncy of the antenna, as suggested in your email below. Shouldn't this lower the resonant frequency?

Hope you had a good time in NYC. I live about 70KM east of the city on Long Island. Thanks.

Harvey, WA2AAE

2811. Hello again

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-11-26 20:39:47 UTC
From: John
Topic: 2811 Message: 2811

Hello Hexbeambuilders,
Its long ago I posted on this site; busy job and
family-pericles keeps me off posting. In feature I will looking more
again. Wanna let you know Im also busy making a website of my radio-
hobby with Hexbeam-pages how I build my first one and assembling my
second one with glasfibres-fishingpoles, but went wrong. Till my site
is uploaded you can look in my photo-album at yahoo to see my step by
step building of this antenne wich has giving me lots of DX. THe URL
from this photoalbum is:

http://pg.photos.yahoo.com/ph/johndeilander/my_photos

Hope you have info enough to build this fabalous antenna.

Best 73's de Jan PA2JJB

Hey John thank you for the link. It is very useful for
any new beee to decide and start building a new
antenna like the one you have built.

2813. Traffie Hexbeam - durability question...

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-11-28 05:56:57 UTC
From: wb8yqj
Topic: 2813 Message: 2813

Hi Guys,

The HXL-20 (lightweight 20m) antenna was awesome this weekend for the CQ WWDX CW, Europe has been very difficult from SoCal using the GAP vertical but the 20m version of the Hex allowed me to work even the EU stations that seemed weak on receive - not so with the GAP. 5db is alot when you are frequently operating on the margin.

There is some string used on this antenna. Having removed the previous antenna after 2.5 years and seeing what the sun damage did to the tie wraps, tape, and coax, it made me wonder about the string on the new antenna.

Anyone else have this antenna up for a couple years or more without needing to restring it?

Thanks in advance,
Don WB8YQJ/6
Carlsbad, Ca.

2814. Re: Traffie Hexbeam - durability question...

I think Traffie uses Dacron which has excellent sunlight resistance and low stretch. I used nylon in mine but that will change as I move toward a more permenant version.

An old Cushcraft R7 I have used plastic cable clamps to stabilize the capacitor rods. After 7 years outside, they are very brittle. Newer versions now use custom machined blocks (Delrin possibly but I'm not sure).

It does pay to start replace the UV damaged elements before things really fall apart.

Hi Duke,
I may be interested in some toroids (let's say 10) for the next HX-5Bi that I'll purchase (using 9913 coax cable). i may not need them, but in case of, I'd rather like to have some...

Would it be possible for you, if you still have some available, to sell me some of them. I'll pay all shipping fees of course.

In advance, thansk for your answer,

From: Tom King
Topic: 2804 Message: 2817

What size electrical conduit did you use? I'm considering using schedule 40 3/4 or 1 inch size. What did you use for the center plate and the center verticle section? please keep us informed on the durability of the electrical conduit.

Anybody find a source for 10 foot fiberglass poles in the northwest USA?

2818. hex-beam parts list and tubing information

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-11-28 15:43:14 UTC
From: Kevin Adam N9IWW
Topic: 2804 Message: 2818

gander mountain has up to 20 foot buddy shakesphere poles that work great
if just making 20-10m contact http://www.mgs4u.com/ max gain systems he has
what you need for less than 100 bucks shipped to your qth

These are the Tubing dimensions I used that work out. They are from Max-Gain
Systems, but only buy the 8 foot lengths, UPS will be considerable more, but the
length and sizes work.
Qty. Size Length
6 3/4" 8 feet Tubing
3 1" 8 feet Tubing
1 1 1/4" 8 feet Tubing
1 1/2" 8 feet Tubing
Cut the 1 1/4" Tubing to make 6 pieces to go on your Hex base plate wirh U-Bolts
and add the other sizes accordingly. By the way I used
1 1/4" U-Bolts and had to stretch them a little over a piece of barstock to fit over the
Fiberglass Tubing. Only use the 1/2" tubing cut in 6 pieces if you need a little more
curve at the end, it isn't necessary, some people like it better.
Wire I used was 14 Gauge Flex Weave 167 strand from Rf Davis, a little pricey but
excellent wire for the project.
Band Driven Length Reflector Length End Spacings
20M 219" 222" 5" & 7"
17M 169" 172" 3.5" & 5.5"
15M 145" 148" 3.25" & 4.75"
12M 122" 124" 2.5" & 4.25"
10M 109" 111" 2.25" & 3.5"
These are usually within a couple of inches in being tuned correctly.

Mast Spacing (Approx.) From SO239
20M 1.25" 17M 17.625" 15M 22.625" 12M 27.88" 10M 30.25"
The bottom of the center section is wherever the 10M lines look straight. Go up
from the with each to find all band straight rather than the mast spacing dimensions,
they are close but may vary a little. Even if they are not straight the antenna still
should work OK most of the time. Note the wire dimensions are for one leg side
only, so you will need two of each of these cut. The Aluminum Hex
plate I made was 12" and 5/16" thick, but 1/4" and 9.5" across the flats is good
also. By the way you tip spacing at the top will be around 113" for 20 Meters wire.
Now maybe this will give a few builders better insight. If anyone would like it I can
tell you how to do the center pole and Feed connections too. Jerry Farek N5GND
check out my photo section (N5GND) thanks to N5GND for this information.

2819. Re: [hex-beam] hex-beam parts list and tubing information

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-11-28 17:43:03 UTC
From: dave@zievid.com
Topic: 2804 Message: 2819

FWIW, I just put together a 5 bander with MaxGain poles as well. I used 4' 3/4" sections at the base, then 2 4' 1/2" sections going out to the tips. It seems strong and gives enough tension to pull the wires into shape.

The extra shipping cost for 8' poles is high, so you can get them cut to 4' and save a lot. I cut some short sections of 3/4" (get an extra pole) and glued one (about an inch long) as a stopper 6" up on one 1/2" pole. This becomes the middle 1/2" section which slides into the base 3/4" pole. For the top, I used a 10" section of 3/4" glued to the base of the outer 1/2" pole so it slides over the middle tube.

It certainly would be possible to use 1" or greater tubes at the base and use this approach to taper going out. I ended up with this arrangement after experimenting and finding the 1/4" solid rod does NOT give enough tension to hold the 20m wires firmly.

This sounds more complicated than it is. I hope to have some pictures up soon that will show it better.

2820. Re: Its together & working

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-11-28 18:09:25 UTC
From: n3gnw
Topic: 2804 Message: 2820

I used 1/2 inch (inside diameter) PVC electrical conduit. Its stamped UV resistant. It needed 1/2 inch wood dowels in it to stiffen it up and still needs some shape adjustment. Since its outdoor and underground rated, it should hold up for years in the elements. I am planning a second version with fiberglass spreaders someday.

For the center mast I used 6 feet of 1 1/4 inch wood closet clothing rod with a water sealer on it. The screw eyes hold the ends of the antenna wires to it and that's where they shorted. I am planning on replacing this with a 1 1/2 inch piece opf conduit and feeding the elements from the inside.

For the base plate I cut a 12 inch diameter circle out of 1/2 inch pressure trated plywood.

73,
Mark N3GNW

P.S. when I can get to the pictures section, I'll upload the ones I've taken.

Hi Mark

I am sure that U will like the performance of the beam. I have had on at my (warminster) QTH for about 3 months. It never lets me down...amazing performance for such a small package.
I have it up at about 38 feet, on a Rohn push up tower. All bands work very well.

Mine was not homebrewed..I did the Traffie thing. Just did not have the time to home brew. But glad to hear yours is comming along !

I just bought six crappie poles at this site. They look really good to me and I am constructing a single band 20 M hex beam as my first. I don't plan to put any tension on the poles for this single bander. The poles are very light.

My previous message didn't include the link to the site for purchase of fiberglass crappie poles. I bought six of them at www.bnmpoles.com and they are easily less than a pound each. Seem pretty strong and I am getting ready to construct a single band hex beam. If successful, I will expand later to multi-band.

Somebody help me. DL7IO's design for the hexbeam indicates 1,5 mm2 for the wire. I assume this means cross section of 5 mm square, which translates as best I can figure to 10 gauge. Is this right?

2825. Re: Its together & working

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-11-29 03:37:33 UTC
From: n3gnw
Topic: 2804 Message: 2825

I used 14 American Wire Guage wire for my driven and reflector elements. I think I saw a note that Holger used 16 guage wire but I don't know how European wire guages compare with ours (probably similar but metric based). 16 is smaller and lighter than 14. 1,5 mm2 is not really that big. Don't forget its Pi*(radius)squared.

For the low impedance feed line I used 6 AWG which was a little difficult to work with but more than 4 mm2 in cross section.

Hello K4KIO,
the wire I used has an area of 1.5mm² or a diameter of 1.38mm or 0.054in.
But this is not critical. You easily can use bigger diameter. A serious effect on the length has any kind of insulation as this will lead to shorter elements (2-8%, depending on the kind of insulation).

By the way. I highly recommend to not (!) use PVC insulation. PVC is hf sensitive and gets hot if you run power. While using "legal power" the insulation may get damaged (fluid). With 100W or less this may not be critical.

And also I would not use PVC tubes for the spreaders. PVC is not strong enough (mounting/fixing), has no elasticity (tension for wires/shape of antenna)and is never UV resistent.

This is not saving money but wasting as you have to built twice.

Mark and Holger

Thanks for the info on the wire size. I had interpreted the 1,5 mm to mean that the cross section was 5 mm squared, a very thick piece of wire indeed. I guess the german decimal mark is a comma instead of the period which is used for the decimal mark in English. Anyway, thanks for clearing that up.

And Holger, I am not using PVC for spreaders; that stuff is ok for some things but not for hexbeam spreaders.

Leo, K4KIO

I've been assuming that UV stabilized plastic electrical conduit is form of PVC, but is it? I'll try to check my spreaders in the dark and pouring rain tonight.

Try your local farm and ranch stores. There are several makers of fiberglass electric fence posts that supply several diameters (3/8" and 1/2" are good) and in lengths from 48" to 84".
These posts are simply fiberglass rod with slightly sharpened ends. Unfortunately, all that the stores carry in my local area are the 3/8" by 48" posts. If the stores in your area carry the longer posts you can figure out a way to splice them into whatever length you need. I contrived plastic adapters (I cut strips of 3/4" thick HDPE and drilled 3 inch deep 3/8" holes in the end of the adapters) to splice and lengthen the 4 foot 3/8" posts into spreader lengths of 9' 10" to build my HexBeam. My posts and the plastic splices fit together much like the old wood Tinkertoys did. I did glue them together for a more robust construction, though.

Well I checked them in the morning when it was a lot dryer and they
are marked PVC, UV resistant, above and underground use.

2834. Re: [hex-beam] Re: Its together & working

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-12-02 02:47:23 UTC
From: buysmart2002
Topic: 2804 Message: 2834

I got six of the BW4, 13 foot poles for $11.83 each. The first three sections extend to about 122 inches so I don't need the fourth section as I am building a 20-10 five band system. I am inserting a 1 inch wood dowel about six inches long in the large end and bolting the dowel to the wood base plate. It's very strong and this way, I don't use U bolts and bring any crushing pressure on the pole.

If you are going to build a 20 meter hexbeam, I would not be tempted to buy the 10 foot crappie poles to save a few bucks because the last section is really not stiff enough to do the job. Go ahead and get the 13 foot poles and just use the three larger sections.

I just shoved the last section back into the pole; it weighs very little and it looked like too much trouble to get it out. The far end of the third section of the pole is 1/4 inch in diameter and I stuck 1/4 inch wood dowel about four inches long into the end of each. This makes it possible to tie to the end without cutting a hole in the pole itself thereby weakening it. I have drilled a small hole in each dowel to use to put a small homemade copper link in it that will be used to tie the nylon cords to (there will be three cords at this junction point, one to the center pole and one each to the adjacent crappie pole).

The poles when extended to ten feet can be bent up without any apparent stress (they are fishing poles afterall) but have enough rigidity that I am confident they will support all the wires (which will be 16 ga stranded, non-insulated) using DL7IO measurements.

I am painting all wood parts and using galvanized bolts.

The mast is inserted through a 1 5/16 hole in the center of the base. The mast is connected to the base using three simple 90 degree angle brackets. I am using a hose clamp to pull the brackets against the pole so there is no need to drill through the mast and use more bolts. This will make it possible to easily slide the base up and down the pole for minor adjustments as necessary.

To anchor the antenna wires to the poles, I will use a cable tie wrapped onto itself to form a loop with a long tail. The tail section of the tie will be taped to the pole. This way the antenna wire can slip easily inside the loop as needed. Guess it will take about 30 of these for a five band system. (6 per band).

Sorry, you asked what time it is and you got the design of the watch.

All the best,

Leo, K4KIO

Part of my justification for building the first is that its a prototype and learning tool. It needs improvement to withstand more than a couple of months of use. So your explanations give me a lot of ideas.

How do you mount the base plate to the support post (not center feed post)?

73,
Mark

2836. Re: [hex-beam] Re: Its together & working

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-12-03 18:03:40 UTC
From: buysmart2002
Topic: 2804 Message: 2836

Holger, I am building a 20 M hexbeam using your design measurements. They are very helpful. However, I have a question. The reflector element is longer than the driven element. Also the end spacing for the reflector element is greater. Does not this mean that the reflector element and the driven element must be in slightly different planes?
I installed the driven element first and am finding that the reflector element has too much slack in it. How is this to be dealt with?

The only solution I can find is to place the reflector element in a slightly higher plane than the driven element. Is that correct?
Thanks for any help.

dl7io <dl7io@...> wrote:
Hello K4KIO,
the wire I used has an area of 1.5mm² or a diameter of 1.38mm or 0.054in.
But this is not critical. You easily can use bigger diameter. A serious effect on the length has any kind of insulation as this will lead to shorter elements (2-8%, depending on the kind of insulation).

By the way. I highly recommend to not (!) use PVC insulation. PVC is hf sensitive and gets hot if you run power. While using "legal power" the insulation may get damaged (fluid). With 100W or less this may not be critical.

And also I would not use PVC tubes for the spreaders. PVC is not strong enough (mounting/fixing), has no elasticity (tension for wires/shape of antenna)and is never UV resistent.

This is not saving money but wasting as you have to built twice.

Hello Leo,
The reflector ens spacing is shorter than for the driven element.
It may be 1 value for the overall spacing and 1 value for reflector
or driven element spacing only.
In every case the reflector end isolator is shorter than for the
driven element.

2838. Wire Lengths??

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-12-03 22:50:23 UTC
From: ki4jwy
Topic: 2838 Message: 2838

I am in the process of building a 5 band HexBeam. The HexCalc program shows for 20 M a driven element length of 438.30" and a Reflector element length of 445.53".

I see another hexbeam on here with the following lengths:
Band Driven Length Reflector Length End Spacings
20M 219" 222"

Is the bottom figure for each wire from the screw to the tip or what?

John Cowan
W0TMM

Topic: 2838 Message: 2839

I used Holger's metric meaurements converted to english. He is careful to point out that the measurement is for each leg and you need two legs for the driven side and two legs for the reflector side. I have not stared closely at the HexCalc values but they appear to need to be divided by two (or just cut the wires in half). 219 and 222 are almost exactly half of the HexCalc values you give.

For all of the legs I added four inches for tuning. I needed about 3 inches of it on 12m. All of the other bands needed some shortening.

Hello John,
yes it does.
The lengths of the feeding line is part of the radiator.
It should not radiate intself as it is a parallel line. But the
elements far away from the feeding point have shorter lengths as they
would have with direct feeding.
If you feed from the other side the element dimensions are different.

John,
HexCalc is a tool to calculate single band coordinates for the higher
bands.
It does not give dimension for multiband designs. You better check
the designs I published. This are multiband designs.

John,
this must be an old photo. I made only one center post with just 1 connection point for both reflector legs. This was the first beam with inside installed feeding system (ser. No.3). All others have 2 srews and a small wire bridge to connect both legs is in the inside. I have detail photos but will not be back home before Friday night/Saturday.

Have you checked the photos of R1MVW (www.r1mvw.com). They used a mechanical hexagonal design to implement 3 elements. I will model this for extensions of the higher bands in the 40m multiband designs if I find some time.
It could be a 2 element hexagonal beam for 40/30m and a 3 element for 20/17 and may be 12m.

So it will be a combination of the hexbeam and a spiderbeam.

Holger:

I am confused about the feedpoint for your design.

Your photos on your web site show the multi-band hexbeam is fed from the top. But the notes on the design data files show that the multi-band hexbeam is fed from the bottom. Which is correct? Feed from the top or feed from the bottom?

Could you please make this clear?

Thanks.

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-12-07 15:33:55 UTC
From: dl7io
Topic: 2840 Message: 2847

Hello Leo,
this is easy to clarify.

The published 5 band design for 20-10m is for top feeding at the 20m element.
All other published designs (40m+ versions or 20m+ versions) are fed at the bottom or at the lowest band by mechanical installation, highest by frequency.

I could not see any advantage for top feeding. So all new designs were made for bottom feeding.

2848. NEW HX5Bi Beam Installed

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-12-08 16:38:01 UTC
From: Duke - NA1A
Topic: 2848 Message: 2848

I just put up a brand new HexBeam (HX5Bi) at N6SFD's QTH in Santa Monica, CA. The antenna is mounted on top 10 ft. roof top tower on a 300ft. tall buiding.
SWR is flat from band edge to band edge on every band with the exception of 17M - 1.3:1 SWR.
On the air test compare to previous antenna which was a Cushcraft MA5B (on the same tower), the reports were a substantial 4-5 S-units higher.
On the long haul, we could hear European (Italian station) at an S-5 where as on the Cushcraft, he was not audible.
Looks like the HexBeam does the trick again.

Hi,
I read with interest your email..I have bought a HX5Bi...yet to be put up due to weather here in Idaho...but with my chat with Mr. Traffie ...he lead me to believe that if I had put the antenna on the push up pole mounted on to or next to the garage that has a metal roof...that the antenna would act as if it was only 20' off the ground compared to the 40' ... if it was on the pole and in the clear..so I have tried to put the antenna up in the clear but could have been up by now had I had gone to the antenna been mounted to the side of the garage instead of doing guy wire achors in the frozen ground.. Thoughts/comments???

2850. Re: NEW HX5Bi Beam Installed

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-12-11 22:35:06 UTC
From: w4wb
Topic: 2848 Message: 2850

Traffie is basically correct assuming your roof is 20' high and really big and flat. My Hex-Beam is on a push-up pole near the end and above a FLAT metal roof at 11'. Antenna is at about 36'. The roof is 30' wide and about 150' long. Do I notice a difference as I rotate the beam. Yep. Is it much. Nope. SWR is FB. Does it work okay. Well over 250 countries/entities with it. If your roof is not too large, then the effect of the roof is less than if it were really large in area.

73,
Barry W4WB

I can not speak to the relative capability of the Gap Titan. I do have a Hexbeam story, though. I helped a local Ham build and raise a Homebrew 20 meter Hexbeam this summer. His chief antenna was previously a vertical Hustler 5BTV, which he liked and used successfully. On the design Band the Hexbeam is much quieter and he has frequent easy conversations wjth Hams he can barely hear on the Hustler. I hasten to add that given the right conditions the Hustler is still the antenna to use, but, he really likes his Hexbeam. I also have a 5BTV which I like. As a matter of fact, as soon as I have breakfast I must go out to the shack/shop and complete rhe erection (30 feet) of my own homebrewed 20 meter Hexbeam. I raised it last evening to see if I had it functional and this morning I've got to weatherproof my coax connection, reraise the mast and place the ties for the coax and rotor cable. I hope to use my Hexbeam as successfully as my friend uses his. For some good Hexbeam info, try the website below.

2853. Hex Beam VS Log Antenna

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-12-13 17:17:13 UTC
From: Duke - NA1A
Topic: 2853 Message: 2853

On air signal comparison on 20M - Dec. 13th, 2005:
I was in a QSO with two stations in WA. They are about 20 miles apart. One station was using the HX5Bi at roughly 40 ft. His signal strength was 10 over S9 runing barefoot. The other station ran a 9 element log at 70ft. with 1.5KW of output power. He was 20dB over S-9.
I asked the station with the 1.5KW and log antenna to turn the linear off. Once he did that, his signal was the same as the station running the HexBeam with 100W at 40ft.

From: n3gnw
Topic: 2851 Message: 2854

I temporarily put up a home made 5-band version for CQ WW CW with the antenna base at 23 feet (its down now and I'm planning structural improvements to it). It consistantly gave me 2 S units (as read from my TS-850's meter) over my Cushcraft R7 vertical. There were very few pileups I couldn't break in 2 or 3 calls, many in one call.

Due to the PVC I used for spreaders, the elements were not aligned as well as they could have been, so I expect somewhat better performance when I switch to fiberglass spreaders.

It was worth the effort to build it and put it up.

73,
Mark N3GNW

From: wb8yqj
Topic: 2851 Message: 2855

I have the GAP Eagle, and have operated one since 1993.

At my QTH it's ground mounted and equivalent to a dipole at 30 feet for the bands it covers. Exclude 40m where the physical length of the antenna is insufficient.

My 20m hexbeam at 35 feet is normally two S-units better than the GAP and maintains that level without nearly as much fast QSB as the GAP. The hex also has less QRN.

I still like and enjoy the GAP for it's durability, ease of installation, and band versatility. Mine is painted green, never needs to be turned, and attracts no attention at all to my place. But it's no match for the hex beam.

Two years ago, I bought a used 17M mono band HexBeam and did an A-B test against an R-7 vertical.
At first I had the Hex up about 18 ft and there was very little difference in performance. After raising the Hex to 28 ft, it was always far better than the R-7. The Hex only weighs 6 pounds and it doesn't move in the wind. The R-7 would lean over 30 degrees in the same wind. I use a TV mast and TV rotator (cheap).

Some day I hope to buy a 5-band Hex, but at 19 pounds i'll need a better mast and rotator.

I had an R-7 vertical up on my 50 ft tower at one time. Not only that it worked very poorly in all directions, but it also threw out RFI like there was no tomorrow. A guy way down the block even complained about hearing me on his telephone.
I got rid of this R7 after about a week and got the HXL-17 by Traffie. It worked so well on top of my W51 tower, so after a year, I replaced it with the HX5Bi. It's the right choice.
The only other antenna I would consider getting in the future would be the 40M HexBeam on a seperate tower (that is if I could get the approval from the XYL to put up a second tower...)
BTW, an el cheapo $60 Radio Shack rotator is all you'll need to rotate the 5 bander HexBeam.

I use the hex/ 5 bander at 40 feet. And a Rohn 40 foot push up mast. It spins with a regular channel master rotor, and a neat little digital controler. It is guyed at the 25 foot level. and again at the 35 five foot level. I am in the Noth east mid atlantic area...and it has seen 50 mph winds with no real movement at all. Works very well for a small beam. Does not give up much performance to most quad designs...but still not in the same leagues as a full size perodic etc.

Hi Tom

That is where I was, before I bought the Hex. I woule believe the two element Stepir is on bar with the hex, in performance. But it does offer you 6 meters, if that matters. I do , however think the 3 element stepir is a better performer. Hard to beat a full size Yagi...that is always resonant. It certainly has more gain, and a better front to back .

But ...as you said. Hard to beat the small foot print...vs performance. And not to mention light weight, and wind loading. Ease of install? I put mine up by myself...using a 40 foot push up mast...Choose your weapon? I think I would buy another...

I lucked out for once in my life and won an old Ameritron AL-80 amp at a Frankford Radio Club meeting. When asked if I would get it on the air for the upcoming CQWW CW contest I said I was concentrating on the hex beam I was building and I already had an 811H amp. Everyone said get the beam done. Since I had an almost as powerful amp, the beam would give me more bang for the buck.

So any beam is better than none.

I'm now looking at a old but in good shape Rohn 6 tower. Should be more than enough to hold up the 5 bander.

unless your space is limited, why even bother comparing!The stepp will out talk it...especially the three elememt step...Lets face it ..All of us love the hex for its smmall foot print but it is a good COMPROMISE antenna...ITS NOT A FULL SIZED OPTIMIZED INOSPHERE BLASTER!...But in any hams arsenal both types of antennas have their application and place...The better question is do you have the space or the resources to fund the stepp install ...they ain't cheap! A hex however installed can come in under $400 installed if you can homebrew!!!You will also hve something you did!...So thats the best advice on this comparion I have!.....73 MIKE...KC4JMH

They can be had even cheaper, My homebrew 20 meter monoband cost $65 to build and another hundred for 30 foot mast, UV resistant guy rope, new rotor cable and coax. Already posessed an AR-40 rotor (left over, dare I say it, from the CB days of my wasted youth). Better yet, the 20 meter Hexbeam turns out to be resonant on our local 2 meter repeater frequency and is usable even with the dreaded polarity disparity. I can work the repeater (15 miles away) with 5 watts easily. Guess having the antenna 30 feet high helps, not to mention the low hill upon which I live.

Hi All,

I have HEX-Beam #28. Its been up on a 40 ft tower since 3/27/2000 thru high winds and ice storms in central Massachusetts with out any problems. I have been able to work any DX station heard with it and a Yaesu FT1000MP and Ameritron 811H. My location is in a valley 100 ft below the surrounding hills.

The SteppIR is a marvelous antenna but, if you're married, you had better have included monster antennas in your prenuptial agreement. The 5 band Hex is more likely to keep everyone in the family happy. It has survived the Minnesota ice storms and 80 mph wind. Merry Christmas. Ed, N0OQ

I contacted SteppIr and asked if they had considered a vertically oriented yagi with 3 elements where there would be 2 elements active at any time and direction would be selected by the software selecting the active elements. Similar to the old CB Super Scanner antenna except that they used one driven element and dual reflectors. Then the footprint of the antenna would be reduced considerably and it would not need to turn.

But they are making money hand over fist on their existing yagi or vertical product and trying to fill orders. So hexbeam seems to be the only game in town. That's fine here, all I need is one good option. The hexbeam has provided a presence on 20m that I never had before in 30 years of amateur radio.

2871. Comparison tests of Hex Beam verse other Antennas

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-12-18 22:07:19 UTC
From: acbdzw
Topic: 2871 Message: 2871

I have had for the last 6 and a half years a Gap Titan Vertical and for the last 5 and a half years an HX5 Hex Beam (serial #081).My Gap Titan Vertical is approximately 20 meters from my house on a 2 meter mast on the Gap tilt over ground support. My Hex Beam is on a Glen Martin 1.75 meter roof tower. The Hex Beam is approximately 3 meters off my roof and about 12 meters off the ground. I run barefoot and also have a kw . I have made tests over the years just running 100 watts and with the
kw.
As far as vertical antennas go I think the Gap Titan is a good vertical antenna.This is evidenced by the mostly favorable reviews the Titan has received on eham.net and from personal experience with the antenna. .My only complaint with the Titan vertical is mainly on 80 meters where it is not a good antenna. However I knew this when I bought the
Titan.
But the Gap Titan vertical is no match against my Traffie Hex Beam on 10 -20 meters and the warc bands. I have consistently received reports, making tests running barefoot and with the kw on both antennas, of from a 2 to 4 S unit difference in favor of my Hex Beam over the vertical.However in reality you cannot compare a Hex Beam which gives gain and has an fb ratio to a vertical which is a multi directional antenna with a low angle of radiation but without much gain. Thus you really cannot make a fair comparison between someone using a Hex Beam and someone using a vertical from the same location. The Hex Beam ,all things being equal,should outperform the vertical all the
time.
I have room at my QTH for a tower in my backyard and a much bigger antenna than my Hex Beam and roof tower. However I wanted a low profile antenna that my xyl and neighbors would not object. This I have with my present set up and I am
satisfied .
In general if I can here a station on my Hex Beam I can work them all over the world, especially when I run my kw.I mostly operate SSB but occasionally go on cw.I use my vertical mostly on 30 and 40
meters.
In the past at other qth's I have had for a number of years a Mosley Classic 33 triband beam and a Cushcraft A3 tribander. It is my opinion and I have not run any tests on this, that my Hex Beam works out just as well if not better than your average 3 element tribander on a small boom such as your TA33 by mosley, Acushcraft, TH3 by Hy Gain and C3 by Force 12.The Hex Beam also covers the warc bands and the average tribander does not cover these
bands.

I have made comparison tests with friends who are using the KLM Kt34xa antenna and the Step IR 4 element antenna on 15 meter towers. Running the same power those using the 4 element Step Ir and KLM KT34XA consistently got reports of about 2 S units more than I got. But remember their antennas are much bigger and much higher than my little Hex Beam which theoretically is only equivalent to a 2 element beam. Mike Traffie has also told me if I put my Hex Beam up higher and gotten it away from my house I would probably work out better. However I am satisfied with the antenna the way it is at present.

Several years ago World Radio Magazine had the only comparison test of a Hex Beam comparing it to another antenna under similar conditions. I forget which issue it was in but maybe another member of this group can post more about this test. According to my recollection the test site was in New Hampshire. The Hex Beam was being compared to Mosley TA 32 2 element beam.Both the Hex Beam and TA 32 were on towers approximately 20 meters high about 30 meters from each other . The test was done just running 100 watts.

If I also recollect correctly the test was only conducted on 20 meters. There were two receiving stations. One was in the Detroit Michigan area and the other in Los Angeles California.The results were interesting. The Detroit station who was copying the signal on short skip did not notice any difference in signal strength between the TA32 and the Hex Beam.However the Los Angelis station on a longer skip gave the Hex Beam an advantage of 2 S units. This is the only test under similar conditions that I know between a Hex Beam and another beam antenna.

I wish this test would have been made against a 3 element tribander instead of the 2 element TA32. I still think the Hex Beam would have come out better or at the very least just as good on the longer skip.

I am not going to put down the Step IR antennas because they are very good nor will I put down other good antennas such as the Optibeam or similar antennas. For those that have the space and funds to purchase these antennas they work out very well. Most likely these larger antennas should work out better than the Hex Beam.

However I wish someone or organization like World Radio would make comparable tests . I am curious how the Hex Beam compares to the 2element Step Ir antenna. I would think off hand the 3 element Step Ir is better but not the 2 element model. However I know of no tests that have actually compared the Hex Beam. to these other antennas nor to your average tribander.If someone wants to make these tests I think it would be greatly appreciated by the Hex Beam community in particular and the rest of the amateur radio community in general.

Again from my own tests the Hex Beam is at least 2 S units better than my Gap Titan Vertical. However stations using larger multiband

antennas and mono band antennas including the 4 element stepIr get reports of up to 2 S units better than my little Hex Beam. 73 and wishing everyone a happy holiday season-Alan-K2ACB

Ok, I'm now convinced to purchase a Hex Beam.
What has the group found to be a great 40 and 80 meter antenna to complement the Hex beam?

Hi Tom,
the best would be to use a Hexbeam at 40m or minimum 30m (100ft.)
height. I'm still looking for a beta tester with this possibility.

I can't presume to give advice on possible great 40 and 80 meter antennas to complement the Hexbeam. There was a recent QST article on a crossed 40 and 80 meter inverted vee NVIS antenna that you might consult. I am using a brand new homebrew 20 meter hexbeam, though, and I've discovered my MFJ-948 tuner will tune the Hexbeam down to 160 meters and up to 15 meters. It'll probably tune everything between 10 and 160 meters, but I've not tried the bands above 15 because I've not heard anything on those bands to try for. When raising my Hexbeam on a 30 foot mast last week, I used a MFJ-369 analyzer and was pleased to find that the Hexbeam was resonant on 2 meters as well as 20 meters. I don't have any idea this early in my usage of the Hexbeam how effective using the tuner on the other bands will be, but I intend to find out.

I am using the 80 meter windom from www.packetradio.com. I am VERY happy with it. It is very well made and I don't have to use a tuner with it. Its about as cheap to buy one from packetradio as it is to homebrew using equally good components.

It is much better than the G5RV I had up before. I like it better than a band specific dipole too. I have never had a fan dipole so I can't comment on that one. I don't need to try one now that I am happy with the windom.

I have the Hexbeam on antenna port 1 and the windom on antenna port 2. I now wish I had 2 amps! Perhaps in the future I can add a Toyko Hy-Power amp to the Hex port and keep the 811h on the windom port.

The Hexbeam has been my best ham product purchase ever.

You won't regret getting the Hexbeam!

I posted some pictures of the MkI (Mark 1) hex beam I built. Depending on how much I get done over the next week or two I will either have the MkIa or a MkII.

With apologies to all hams who regularly use metric I have english units here for the materials I used.

The base plate is a 12 inch diameter circle I cut from 1/2 inch thich pressure treated plywood. The 1/2 inch inside diameter PVC electrical conduit is held on with PVC conduit clamps. The conduit is 10 feet long and I put 8 feet of wood dowel in it to stiffen it up. Overall I have to agree with the other comments that PVC is not a good choice for spreaders.

The center mast is 1 1/4 wood closet rod. The feedline is 6 AWG. I put smaller guage wire taps at the appropriate points. Screw eyes into the wood act as attachment points and strain relief.

I used hose clamps, tie wraps and PEX tubing to attach the elements to the spreaders. This is going to get simplified to just dual tie wraps. The ends of the elements are folded pack and held in place with cable clamps. This leaves a little loop at the end to tie off at the correct distance with some twine.

The current version ran about $100. Not a bad price for the
performance I got on 5 bands.

Folks,

My checking for new member pending postings may be at times longer than 24 hours due to holiday activities. Hopefully, this will not cause too much unhappiness.

May each of our group have a wonderful and safe holiday season, and a fine New Year.

73 es Merry Christmas,

Thanks. Well, I shoudda shot some more photos.

I used about #6 ga insulated wire and kept it laced together tightly with little cable ties whilst going up the post. One photo shows it fed from the top and that worked best for 20 meters but later I decided to feed from the bottom with was better for the high freq bands.

All bands are connected to the same feedline. No toroids or baluns are used on my hexbeam; although, I have seen others who did use these.

I used solder connections entirely with no other screws, or such hardware. The main thing holding the feed line to the post are the 8 inch cable ties. These things are marvelous for lots of uses on the hexbeam; cheap and effective. Get the ones that are UV resistant since your beam will be in the sunlight.

Hope that answers the questions.

2891. Another "Hex-Beam" Experience

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-12-26 00:26:17 UTC
From: w4wb
Topic: 2891 Message: 2891

FWIW, I had another of those interesting DX QSO's where the DX is weak and I'm a lot stronger. About 1900Z, 5R8GZ was operating a simplex pileup on 14.202. Nice steady operator. Lots of callers. He was working almost nothing but Canadians, some W1's, W9'S, and upper West Coast stations. They all said he was 57 to 59, and 5R8GZ was giving back like reports. At my QTH, he was about 32 at first and then the signal built to mayby 53 to 54. At that point I called him and got him through the pile on the second try and received a 57 report.

Looking at the the propagation program, I again observed this is a reasonable situation given that the receive lobe of the Hex-Beam is higher than the transmit beam lobe (TOA).

As I have said before, if I can hear (distant) DX, then I can work them, even in a simplex pile favoring others.

The Hex-Beam is just two elements, but it sure rocks!

73,
Barry W4WB

Well Barry, I echo your experience. Just two days ago, when I was on 20M with a station back in Virginia. A friend of mine joined into the QSO. This local friend was about 60 miles North of me in the Santa Monica mountains (near Malibu). He ran 1.5KW to a 6 element monobander up 60 ft. My HexBeam with the Alpha 87A also at full legal limit obtained the same signal strength report as my friend in the SM mountains.
Second experienced. I was on 20M talking to a station in the Virgin Islands. A Ham in Santa Barbara (which would be about 150 miles North of me) joined in. He wanted to check out his new 3 element SteppIR and obtained a signal report. He ran 1.5KW and got 10dB over S9 from the Virgin Island station. My HX5Bi and the 1.5KW also got 10dB over S9.
The only other antenna I would consider now is a 40M HexBeam to improve over my Carolina Windom for that band...

Hi Gents..
Yes, I have been noticing the hex's ability to radiate a very potent signal too. Considering it size, and foot print. Very good Dx antenna. I always get better reports than I give...Hope it is not the antenna's ability to hear...rather a great low angle take off

John,
I noticed the same thing when I first put up the HexBeam. Prior to this antenna, I had a 2 element 5 band full size cubical quad by Lightning Bolt (Picture of the old quad can be seen on my website).
I remember with the quad, signal strength comparison against my Carolina Windom (mainly on receive) was about 2 S-unit (stronger on the quad). With the HexBeam, it was usually 3 to 4 S unit, rarely ever a 2 S unit different. A lot of time, I could not even hear the station with the Carolina Windom (or may very little trace of that station's existance), but on the HexBeam, that station was an S-5 somtimes even S-7. This occured over and over to a point where I thought something was wrong with the Carolina Windom...
Recently I put up a brand new HexBeam (HX5Bi) for Fred, N6SFD in Santa Monica, CA. He ran into several similar experiences as I did with his new HexBeam. He was originally planned to put up a 3 element SteppIR and decided against it because of costs, mechanical movements and a few other factors associated with it. He is now very happy that decision and is thrilled with the HexBeam every time he gets on. Freddie can be found on 17M so if you hear him, give him a hauler. Be ready to put on the attenuator :)

Hi All - Top of the Holidays!

I just assembled my HX5Bi on Sat 12/24 - took about 2 hours max to assemble. Currently sitting at 12 feet off the ground.

SWR is between 1.2 and 1.45 on all bands noted - even resonant on 52mhz (roughly 1.5 swr on the anritsu sitemaster , this might change when elevated.

In comparision to my Alpha - Delta Fan Dipole, I am atleast 2 S-units better in the forward direction than the dipole at 30feet. Rotor not installed as of yet, so I am sure this will improve once its 30+ feet up in the air - with the capability of rotating it in the optimum direction.

Mine is still only 11ft to the 20m element and is working great with
a meagre 10w.
The f/b probably suffers at low heights (which might actually be a
plus for a rotatorless hex) and, of course, the take off angle will
be higher, but it makes the contacts and that`s all that counts :)

Happy New Year 2006 to All

I Have a 5 band 10-20 made for me by Holger dl7io, I have always suffered from high qrn here sometimes upto S9.
With the hex the qrn has virtually gone, I am now hearing stations that I cannot hear on the 1/2 size g5rv due to the qrn levels.
It is about 30 feet from the ground on a homebrew mast.
I havn't done to much txing but the few people I have called have answered me.
I normally use 15 watts digital modes and 25 watts ssb.

Just to be able to hear again is heaven for me :-)
I have a buddipole for /p work but now I have the hex I can work from home again.

Have Fun

If you wish to put the effort into it I'm sure it would probably work
OK. If you look in on some of the farm/ranch stores in your area you may
find fiberglass fence posts that will work well for you. In my own area
all you'll find is 3/8" x 48" fiberglass rod posts. In other areas you
may find 1/2" x 72" fiberglass posts. Those can work well for you. I
found a way to make the 4 foot 3/8" diameter posts work for me but, I'd
have much preferred the larger ones.

I see max gain has spreders for $13.00 for 2 spreders 1 inch 8 footer and 1/2 inch 8 footer solid rod that will telescope to make required lenght for hexbeam .Has anyone used these spreders and did you have them cut to lower shipping cost or how did you do it .Any info on these spreders or web sites would be appreciated..Thanks Larry AG8O

2903. Re: [hex-beam] spreders? heres your anwser from a fellow ham

Yahoo group: hex-beam (2001 — 2006)
Date: 2005-12-29 07:53:00 UTC
From: Kevin Adam N9IWW
Topic: 2900 Message: 2903

These are the Tubing dimensions I used that work out. They are from Max-Gain Systems, but only buy the 8 foot lengths, UPS will be considerable more, but the length and sizes work.
Qty. Size Length
6 3/4" 8 feet Tubing
3 1" 8 feet Tubing
1 1 1/4" 8 feet Tubing
1 1/2" 8 feet Tubing
Cut the 1 1/4" Tubing to make 6 pieces to go on your Hex base plate wirh U-Bolts and add the other sizes accordingly. By the way I used
1 1/4" U-Bolts and had to stretch them a little over a piece of barstock to fit over the Fiberglass Tubing. Only use the 1/2" tubing cut in 6 pieces if you need a little more curve at the end, it isn't necessary, some people like it better.
Wire I used was 14 Gauge Flex Weave 167 strand from Rf Davis, a little pricey but excellent wire for the project.
Band Driven Length Reflector Length End Spacings
20M 219" 222" 5" & 7"
17M 169" 172" 3.5" & 5.5"
15M 145" 148" 3.25" & 4.75"
12M 122" 124" 2.5" & 4.25"
10M 109" 111" 2.25" & 3.5"
These are usually within a couple of inches in being tuned correctly.

Mast Spacing (Approx.) From SO239
20M 1.25" 17M 17.625" 15M 22.625" 12M 27.88" 10M 30.25"
The bottom of the center section is wherever the 10M lines look straight. Go up from the with each to find all band straight rather than the mast spacing dimensions, they are close but may vary a little. Even if they are not straight the antenna still should work OK most of the time. Note the wire dimensions are for one leg side only, so you will need two of each of these cut. The Aluminum Hex plate I made was 12" and 5/16" thick, but 1/4" and 9.5" across the flats is good also. By the way you tip spacing at the top will be around 113" for 20 Meters wire. Now maybe this will give a few builders better insight. If anyone would like it I can tell you how to do the center pole and Feed connections too. Jerry Farek N5GND check out my photo section (N5GND)

I have not made the attempt yet , mainly because I am not sure what to use for the speaders. I too would like more info on what type of speader would be the best choice. From crappie poles to tapered lenths of telescopeing fiberglass, graphite rod. I can't afford the traffie one but, I am willing to at least give it a go to make my own. best 73 all

yes i made one 10 Thur 20 meters and i used UV electric PVC (gray) from Lowe's about

9' foot long, and only about $ 2.50 each. you will have to support the ends with a good noly rope or string to the center post just above the top radial,

hope this help, oh buy the way if you e-mail me at w8alc51ham@...

this one is on the ground because i put up a Th6 beam, that x-beam i made from the direction on the yahoo groups page. i also win sweepstakes with it 1 year ago and it made it Thur the ice storm we had.

Havn't done it yet but I plan to. It's really not all that much work. I have used this method on 3 pieces of 1 1/2" water pipe to use as a support for an inverted vee and it did stiffen the pipe up plenty.

I purchased 6" wide strip of cloth then spiral wound it down the tubing. With a roller I rolled epoxy into the cloth and laid it out in such a fashion that it remained straight until the resin cured. Quick and easy enough and no waiting for something to be shipped in across the border or paying exhorbitant broker fees which sometimes happens.

I plan to use 3/4" part length and a 1/2" piece inserted into the end. Will let you know what I think when done. Oh yes I always paint the finished product black or dark green to allow it to blend in with the background trees.

Check your local Farm/Ranch stores for fiberglass rod electric fence
posts ( plain solid fiberglass rod with slightly pointed ends). If you
are lucky you'll find they stock 1/2" x 72"
posts and you'll easily figure a way to splice them to use as Hexbeam
spreaders. Stores in my southern Oklahoma area were only stocking
shorter 3/8" x 48" posts but I was able to use them for my 20 meter
monobanf Hexbeam.

2909. Yet Another Homebrew Hex Web Site

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-01-01 00:53:19 UTC
From: Dave
Topic: 2900 Message: 2909

I'm finally reaching the end of my long hex antenna building project. The 5 bander (20-10m) antenna working, and the web site is up at http://www.zievid.com/W6OT/Hex/Beam.htm with some pictures, graphs and description.

So far the results are good. It's several S units better than my Hustler 5BTV vertical, which is up 15' on a 30x80 metal roof. I haven't rasied the antenna to it's full height yet, so it should get better with another 20' elevation or so. I'm really happy with it.

There are two interesting things about this particular antenna:

a) I used 4' fiberglass tubing from MaxGain, so the shipping costs were reasonable. The web site has the details on how I joined the tubes.

b) I had trouble with feedlines between bands (couldn't get it to play on all 5 bands). I tried several different sets of wires close together as others have described, but I ended up using RG-213 between the wires. This worked great - the difference was measurable, and all 5 bands are now happy. If you're having trouble getting all bands to work, give this a try.

I have a spreadsheet and CSV files on the site if anyone wants to model it in EZNEC. The 12m pattern is a bit off - the gain models slightly higher off the back, so I'll try playing with that and see if I can get it to point in the right direction.

Have a Happy New Year!

- Dave

Good looking antenna, Dave! I have found that my home brew will tune up nicely on 40 meters as well. Home brewed for 20,15 and 6 meters. Not one to make things perfect or maybe just tinkering... I mounted the antenna on a small 20 foot pushup tower. And that isn't cemented into the ground either.. So today I tightened up the bolt that presses on the inner pipe. the rotor wasn't just turning the antenna but also the lower section! Aha!
Still the antenna works great! I do have the hustler vertical and its sure nice to be heard instead of being in or just above the noise floor of each band!
also this group has been a good help for the tinkerers, eh?
Happy and prosperous antenna building for 06!

Great job and nice site.

Did you have to have Max-Gain cut down 8 foot lengths? I don't see
the sizes you mention available in 4 foot lengths.

Yes, Max-Gain will cut their 8' lengths in half. I forget the exact cost of each cut, but it's around a dollar or so. I don't think they sell the 4' sections individually, so you have to buy 8' ones plus the cut and get 2 4' poles.

I think it's buried in the site somewhere, but if I was going to do it over again, I would use 1", 3/4" and 1/2" tubing. You'd need to get 3 8' tubes of each size, and have them all cut in half. Then for the joints, cut 1" sections from the 1" and 3/4" tubes to glue onto the next smaller tubes as stoppers. I ended up with an odd combination because I originally tried 1/4" rod at the tips, and that's not strong enough.

Thanks to everyone for the nice compliments. I really enjoyed this project and hope the info can help others in their building. It's great to have a direction antenna now.

2916. Which antenna

Yahoo group: hex-beam (2001 — 2006)

From: yash@aol.com
Topic: 2916 Message: 2916

Hi to all.
Just set up my new 40 ft. tower , Iam in southwest Florida...cape coral. Need to choose a new antenna. The tower is alum as is the mast and I @64 can nest it and tilt it to the ground...myself... so need to keep the total weight down. Also I have only about a 10 foot turning radius to be able to keep things, on my own property. All that being said,I have narrowed things down to the cushcraft ma5b and the multi band hex beam. I have owned the ma5b while I lived north ..worked very well. All I know about the hex is what I read on the net. some very good and some VERY hard to believe. The biggest factor is the 350.00 versus the 1000.00 for the hex. Since I do not have acess toparts to try to build one or the ambition...have found no complete kits anywhere ,I guess Iam limited to the factory built antenna @1000.00
My question is ... the hex worth twice the cost of the ma5b. ? Is it going to provide that much greater performance?
I realize this is the hex group,so please don't flame me on this ,Iam serious about the question and what ever answers I receive.
happy new year to all
thanks
dale wt4t

I have the Traffie 5 band hex at 42 feet. It works extremely well !

I wish I wopuld have waited, and home brewed one. But at the time I was traveling a lot..and time was not at my disposal. But I find the hex super !

We're obviously biased here, but I would go for the Hex. The MA5B has particularly narrow bandwidth (*VSWR 2:1 Bandwidth: * 665, 110, 255, 100 and 90 kHz. - numbers from Universal Radio's site) so if you like to move around on the bands I think the hex is much better.

The commercial HexBeam's claimed SWR curves are here: http://www.hexbeam.com/performance.shtml and cover the whole bands.

Hi Dale,
I am curious about your aluminum 40 ft. tower. Since you can raise and lower it by yourself, what Model and Brand is it? Sounds like it might be a Universal 40 ft. 4 sq. ft load. I have been looking into something similar.
Thanks

I think it is worth the difference.

With the Hexbeam you will have gain on 12 and 17 that the Cushcraft does not offer. I think the Hexbeam performs better on 10, 15, and 20 too.

You will also have a better built antenna that will be able to stand up to stronger winds. No traps either!

I had to swallow real hard before I plunked down my hard earned cash to send off for a Hexbeam. I have no regrets now... Other than waiting for so long....

I have never heard of someone who regretted getting a Hexbeam.

ALLEN
The tower is a aluma tower,made near tampa florida. It is a 41 foot tower that cranks down to 20 feet,then folds over. Very well made aircraft alum. using a tight welded support structure between the 3 legs. I have a 4x4 alum post 6 feet into the ground and it stands 6 feet high above the ground. the tower has a heavy welded base that is bolted to a 2x2x 20 concrete base via 3 3/8 ss threaded rods embeded in the cement base. that pivits on 2 of the back legs and you can walk it down as easy as a ladder. total weight about 80 lbs. when raised he tower clamps onto the 4x4 post and with a coupla of brackets, it is solid as a rock. Took me only a day to set the 4x4 post and pour the base for the tower ... 6 bags... 60# cement mix total.

thanks

I just ordered my Hex Beam. Mr Traffie suggests 6 type 77 toroids on the coax. The type he sells though, you need to cut off the PL259 and then reinstall. Anyone using a snap-on product that gives equal or better results? who/what/where?

-Hi Dale,
Thanks, that clears things up. Sounds like a neat installation. I
checked out the Aluma web site. I had looked there before but
hadn't noticed the 4X4 aluminum post which makes a big difference.
Should be great to be able to let it down when the wind starts up in
Florida.

Dale,
After reading your article below, I think the HX5Bi is your best choice. I'm in the same situation as you are and that is, I only have just about 10ft of turning radius to one side. The other side, I have plenty of room. This is because where my tower is located (has to be hidden from any windows of the house).
Prior to using this HexBeam, I had the 5 bander cubical quad by Lightning Bolt on this very same tower, the TriEx W51. Excellent antenna, but it protruded over the property line by about 5 ft. After two and a half years, things got ugly with the neighbor so I took it down.
The HexBeam is now mounted on a boom which offset the mounting 5 ft away from the tower. The guy next door can't complaint anymore. I have no windload on the antenna and haven't found any less performance as compare to the 2 element full size cubical quad.
The only complain I have is the damn antenna is too expensive. I got mine used (a year old when I got it) for $500. This should be the price for a brand new one. The Lightning Bolt 5 band quad is only $300!
If Traffie would drop their prices lower, they would make a hella killing with the sales. I think their steep price is not helping their sales too much. As a matter of fact, for a fraction more, one can get a 3 element SteppIR...

2929. Re: [hex-beam] Re: Which antenna

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-01-03 04:04:34 UTC
From: buysmart2002
Topic: 2916 Message: 2929

Dale:

You ought to be able to build a five band hexbeam for under $200 with a little effort. Many on this user group have done it. Mine cost less than $150 using crappie fishing poles.

73,

Leo, K4KIO

HI Dale, you can do no better than a hexbeam, nice small and compact
,works very
good I brought mine with me out of zs to nz
I'm not old only enjoying the traveling life !!

2930. RE: [hex-beam] torroid use

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-01-03 00:20:47 UTC
From: Jim Chaggaris
Topic: 2926 Message: 2930

Tom:

Your best bet is to cut off the pl259 and slip at least 6 (or more) beads.
I usually use 3M 33 or 88 tape then use liquid tape over that.

The snap on beads won't be as effective since each bead should be physically
touching the others.

I just ordered my Hex Beam. Mr Traffie suggests 6 type 77 toroids on the
coax. The type he sells though, you need to cut off the PL259 and then
reinstall. Anyone using a snap-on product that gives equal or better
results? who/what/where?

I think it is worth the difference.

With the Hexbeam you will have gain on 12 and 17 that the Cushcraft
does not offer. I think the Hexbeam performs better on 10, 15, and 20
too.

You will also have a better built antenna that will be able to stand
up to stronger winds. No traps either!

I had to swallow real hard before I plunked down my hard earned cash
to send off for a Hexbeam. I have no regrets now... Other than
waiting for so long....

I have never heard of someone who regretted getting a Hexbeam.

2931. Re: torroid use

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-01-03 07:37:31 UTC
From: w4wb
Topic: 2926 Message: 2931

Tom,

I sure you will be happy with the "real" Hex-Beam. It is worth the money IMO. Sure, one can build one using plywood, fishing poles, and perhaps duck tape, but Traffie's antennas are first-class and will last for years and years. I also note that his are tuned a bit differently than those homebrew ones using the formulas he published over a decade ago. Mike has spent literally thousands of hours over the years learning how to make his antennas perform optimally. And yes, it does make a difference. My special 30-40 m Hex-Beam took him a lot of effort to make it really "sing" on both bands, and sing it does!

To my knowledge, there are no snap-on versions of the Type 73 or 77. I have seen some folks represent that they have such items, but when push comes to shove, they can't verify the material. Almost always, the snap-on ones are Type 43, plus the snap-on ones can harm your coax over time. Frankly, it is no big deal to put on a new coax connector. You can also make a jumper of about say 6' with the beads on it and use a female-female coax connector to your main feed line. Use Coax-Seal or the like of course. FWIW, I use heat shrink to hold my beads in place.

You can also get the beads directly from Amidon.

Enjoy es 73,
Barry W4WB

From: desmoface
Topic: 2932 Message: 2932

Hey gang, looking at the pics at hexbeam's website, it appears that the antenna is omni-directional but it says it needs a lightweight rotor? Am I missing something? Im a hexbeam newbie, of course LOL..thanks in advance.

Hi Steve,
You may be thinking of the cobbweb type antenna,which is omnidirectional.
The hexbeam is essentially a mono or multiband 2 element wire yagi folded into a more compact geometry.
The pattern is quite broad but directional so a rotator is required. In my experience the sharp side nulls of a monoband Hex especially, can be very deep ie: well over 30db+

Not omni directional, it is a 2 ele yagi with the elements bent to make the
footprint smaller

.

very good information on using a laser level , I never would have thoughtof it myself. I guess as soon as I find the poles that will work for me I can start building mine. Thanks to all the homebrewers sharing the wealth of info on the hexbeam. It will help to give me an antenna I will be finally happy with. Being broke and on fixed income it would only be a dream to have something as nice as the hexbeam from Traffie. Thanks again all -----

Hi Guys,

I have the 20m monobander on a 35 foot Radio Shack push up telescoping mast. It was $69 bucks plus the steel guy cable and works quite well enough. The telescoping mast base is pressed in the ground and also connected at house eaves at 8 foot point. I attach the antenna while on a ladder then push it up from the ladder, guys very loose at first.

But I am interested in the multiband hexbeam and that's closer to twenty lbs. with rotor. That's a load to hoist and when it's going up the guys are not yet tight. I've "cheated by" with this kind of arrangement in the past and been lucky going up and coming down. Once it's at height it's no problem however because the guy wires are tight.

Can anyone suggest their optimal solution for getting the 5 band version of this antenna up at 35 feet, while retaining the smallest visibility for the support, in line with the stealthy nature of the antenna itself?

I'd consider some kind of a minimal crank up would probably work best but could be fairly costly - ideas? !!!

Thanks,
Don Rasmussen WB8YQJ

Don,

I don't have an answer to your question as to how to raise a heavier antenna. But I was wondering about the telescoping mast from Radio Shack. Their on-line site doesn't show that mast. Did you get it at a local store or is it one you have had for awhile?

Thanks,

Leo, K4KIO

Hi Leo,
Radio Shack no longer carries the three section push-up mast. They were $69.95 and RS sold them out at $49.95 some time ago. I wanted to get one or two and the guy at the local store looked at the state wide (and Texas is w-i-d-e)inventory and the closest was 100 miles away. This was about a year or 1 1/2 years ago.

Some Lowes home improvement centers carry the Channel Master push up mast. Two of the three near me do. Others might be able to order it.

you mean cell phone shack ;-P they got our of the radio biz long ago and to me are worthless then again they ruined other good radio stores in the seventys by selling junk . lowes had a pretty good one but still ive seen better thicker poles from ham catologs , to me the radio shack pole was thin and not worht the price they were selling it for . radio shack also use to sell a very good uhf antenna for 24 bucks but again they getting out of that biz and inot cell phones and nick knacks . ;-) john kd5dfm
btw ive got a mosley tri bander on a pole with a old alianace rotor . got the rotor off ebay and works well for 20 bucks total ;-) .

Leo, I have had my 35 foot mast for several years now, Radio Shack no longer sells them and you have to find a Radio Shack store that is not near a Mall if you need a rotor or a scanner antenna as well anymore.

The Lowes store near me had the closest match I've found, a 30 foot telescoping mast. That was last month.

Hope this helps,
Don

Don
I was also able to buy a 40' push up pole from Radio Shack. Just go into the store and ask if they can get you one. I live in Northern California

wb8yqj <wb8yqj@...> wrote: Hi Guys,

I have the 20m monobander on a 35 foot Radio Shack push up telescoping mast. It was $69 bucks plus the steel guy cable and works quite well enough. The telescoping mast base is pressed in the ground and also connected at house eaves at 8 foot point. I attach the antenna while on a ladder then push it up from the ladder, guys very loose at first.

But I am interested in the multiband hexbeam and that's closer to twenty lbs. with rotor. That's a load to hoist and when it's going up the guys are not yet tight. I've "cheated by" with this kind of arrangement in the past and been lucky going up and coming down. Once it's at height it's no problem however because the guy wires are tight.

Can anyone suggest their optimal solution for getting the 5 band version of this antenna up at 35 feet, while retaining the smallest visibility for the support, in line with the stealthy nature of the antenna itself?

I'd consider some kind of a minimal crank up would probably work best but could be fairly costly - ideas? !!!

Thanks,
Don Rasmussen WB8YQJ

Leo,

RUN TO LOWES!!!! They are closing them out. I got
during the summer of last year for $9.99. I asked the
folks if they had anymore and they told me they were
no longer carrying anything to do with tv antenna's.
This was the Lowe's in Howell, NJ.

Good luck,

Ray

I used the Lowes, channel master 30 footer. I have since replaced it with a Rohn 50 footer.

The Rohn is a bit sturdier. I also did away with the upper most section. It was too thin for my liking. So it is now at 40 feet. And works great The Rohn was 175.00, but worth the additional cost. And the extra 10 feet doesn't hurt either.

I spin the antenna with a channel master rotor, and a neat little digital control. Very nice compact set up.
good luck

Hello to the group and happy new year!

At my homepage you will fine a solution with a TV-tower, in wich i plan
to put up a home-made HEX-BEAM, I am working on.

Look here: http://www.planker.dk/oz6ym/Mast/default.htm

For the moment i have a full size GP for 40 meter in it, but later.....

I found 6 fishing... in a local auto-teamshop - 6,50 $ pcs.

Next time I am in the Lowes I will look at the part number. I was going to get one but I just picked up 30 feet of Rohn 6. A light weight tower for TV antennas. But it should handle the hex fine.

Its ashame they're closing it out but they are in the business to make money and if doesn't move, open the floor space to something else.

Check the site http://www.leoshoemaker.com/hexbeambyk4kio/general.html
and see K4TIO's unique solution for lifting the Hexbeam into the
ether. He has taken readily available parts to make a fold-over
mounting that is about 26 feet high (and fairly low cost) that folds
down with a winch. He gives details on a hexbeam using Crappie poles
for spreaders and a lightweight rotor for turning. Be sure to look at
the blown up pictures as the details will become clear. He gives a
few ideas to think about even if you don't try to duplicate his
installation.
I notice that the local MDS television people use 30 ft. push up poles
on their installations, perhaps they might be a source of poles.
Seems that everybody is getting out of the antenna pole business, I
remember that Home Depot used to sell them and of course Lowes.
The other option I have considered is Univeral aluminum towers. they
sell 30 ft and up self-supporting towers with 4 sq ft and up ratings.
The smaller 30 ft 4 sq ft tower is around $350 and weighs 38 pounds.
Good luck
Allen KA5N

2953. Masts and Guys

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-01-09 05:45:42 UTC
From: w4wb
Topic: 2953 Message: 2953

FWIW, I noticed several folks mentioning using guy wires to hold masts in place. Wire guys can present RF problems depending upon their lengths. Dacron antenna rope is a fine alternative.

Another point is that one can significantly stiffen a mast by forcing more overlap between the sections. For example, take a 40' mast and transform it into perhaps a 34' mast. It makes a lot of difference in how "floppy" the mast is when being errected and when in use. What I have done is to drill a hole through the overlaped sections and then insert a bolt (with flat, lock, and nut).

73,
Barry W4WB

2954. Homebrewing A Hex-Beam?

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-01-10 00:41:48 UTC
From: jim_ketchum
Topic: 2954 Message: 2954

Greetings to the group,

The more I read the postings here, the more I desire to build this antenna. I was wondering if anyone who has homebrewed one has ordered parts from Horst, DL7IO? If so, was the price difference, including shipping, comparable or cheaper than ordering an antenna from Mike Traffie (not that I would begrudge Mike the business)? Also, has anyone Stateside located similar construction materials equivalent to those that Horst produces there in Germany? I see from his web site that he custom crafts the hubs for his kits. If nothing like it is available in the US, I will have to look at purchasing one of his.

I realize that these may be fairly common questions being asked, but I haven't seen anything so far in the postings that had answered these particular ones. Thanks to all who contribute to answering these questions, and any further ones that may come up in the future regarding this project.

Hello Jim,

I have sent parts all over the world meanwhile. Antennas are installed in Europe and Africa.
As long as we have only small parts, which can be send as a letter, it is easy. Complete antennas or the bigger sized parts are very expensive to ship overseas and that's why it is not interesting to ship to the states.

The center hub would cost you about 200-300 US$ if shipped from here. So therefore there is only marginal competition to Traffie as he has the same problem with shipping costs to Europe.

If you have somebody who comes to Europe and can take this back home for you it might be a chance.

Jim,

If you look through the pictures and descriptions here as well as the web sites that have been listed recently in postings you will see a variety of construction techniques and materials.

Unfortunetely nobody outright lists a set of parts. Some people have gone all the way with a cut and machined metal base like Mike Traffie's Hex-Beam and others have just used plywood or pressure treated plywood like me. But it does encourage creativity.

You can see pictures of the first version I built here.

73,
Mark N3GNW

Jim,

the best baseplate material I found was a polyethelyne kitchen cutting board at Bed Bath and Beyond. It can be cut with a saw, it is very sturdy, it is waterproof and non-conductive. It comes in several sizes; the one I bought cost $6. I tried plywood at first but it would not stand up in the weather.

You can see how I used the cutting board at my hexbeam site.

Leo,
The material I used was akin to the material in your your cutting board. A Ham in my local group works at a rock and gravel quarry where they use 3/4" thick sheet HDPE (high density polyetheline) to line handling chutes. He gave me a scrap piece large enough to cut a hub circle. A 20" diameter circle weighed 6 pounds. I got the weight down to 3 pounds by cutting my circular hub into rounded off six point star shape. I've had the Hexbeam up about 3 weeks now and it seems to be standing up well. I even tested its toughness one cold morning by striking a small piece of scrap HDPE on an anvil with a large hammer. No chipping or shattering, hardly even made a mark. I'd been worrying about the effect of low temperature on the material and feel better about it now. By the way, the spreaders I used with the HDPE hub are fiberglass electric fence posts (round fiberglass rod) I got at a local farm/ranch store. Mine were 3/8" by 48" and had to be spliced to get a proper length. I have found from speaking to other Hexbeamers that some area farm or ranch stores carry 1/2" by 72" fiberglass posts. Sure wish the stores in my area had stocked that larger size.

Harold,

Great ideas for spreaders and baseplate.

On another theme, I just visited the local Lowe's here in Birmingham, AL and they carry the Channel Master lineup of TV antenna hardware including the following:

30 foot telescoping mast in three sections with guy ring hardware $44.83
10 foot section for extending above mast to 40 feet (don't remember price)
Rotator $90
Rotator control cable 75 ft $10

Oddly enough, I just did a little Lowes internet research yesterday on Channelmaster thru our local store. They don't stock the line here but you can obtain it by special order. If my Radio Shack mast packs it in I'll try for a Channelmaster replacement (actually, the RS mast may really be Channelmaster made). I, and the other local Hexbeamer have our antennas at approximately 30 feet with the one set of guy ropes at about 25 feet. The other local Ham has had his antenna up at least a couple of months longer and his setup has weathered some fairly high winds. I helped construct his hexbeam, he used doubled pvc pipe for spreaders (1/2" inside of 3/4", as I remember). Except for spreader and hub construction our antennas are identical 20 meter monobanders. We got info on the HDPE hub material and found out about the fiberglass fence posts long after we had constructed the original Hexbeam. By the way, I've had a certain amount of success using a tuner to match my antenna on 17 meters. I've got no idea what RF pattern it obtains on that band but it seems useful. It'll tune almost all the HF bands but I've achieved the most contacts on 17 meters.
Sorry about the message length, I tend to get wordy on Hexbeam construction.

Jim,
If you want to look into the fiberglass fishing poles as spreaders, you might check Cabela's sporting good store in KC. They carry the B'n'M Black Widow poles that Leo has used for 9.99 each. My local store in Prairie Du Chien, WI was out of them, but they ordered them from the warehouse in Sidney, NE for me.

Looks like a reasonable price considering the cost of the fibreglass.
The wedges on the baseplate to rake the spreaders higher look a little
suspect, i guess the spreaders are a bit too rigid to give the correct
curve.

The only other observation is that the assembled hex isn`t shown. Nor
is the element attachment to the spreaders and the wire type isn`t
mentioned.
Other than that it could save someone the time to homebrew one :)

My homebrew Hexbeam 20 meter monobander is located out at my shop/shack.
At night when 40 and 80 meteres is most active I'm working from the
house on a Hustler 5BTV vertical so can't answer your question directly.
I have had a certain amount of success tuning it to 17 meters however.
Just this week I've had occasion to QSO both east and west coasts and
Puerto Rico on 17 meters. I have no idea how much effectivity offband
tuning allows with the Hexbeam but it does work. Fact is, when I put it
up on my mast and checked it with a MFJ-369 it turned out to be resonant
on 2 meters also, now that I didn't expect.

From: Harold Burton
Topic: 2938 Message: 2975

If your homebrew Hexbeam is going to be built for 20 meters and above,
the individual spreaders will need to be at least 10 feet in length.
Mine (for a 20 meter monoband Hexbeam) were pieced together from
fiberglass fence posts and 3/4" thick HDPE plastic.
They were 9' 10" in length and were just barely long enough.

Hi harold, thanks for the information , I take it as if I want to make the attempt for multibacnd they will have to increase in size then? Anyone know what the lenth minimum is for that? Being I live in New England there is weather to deal with sometimes pretty bad winters here.. Again thanks for all the info everyone, Robin n1zw

2977. dimensions of new spreaders from Max-Gain

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-01-12 19:50:46 UTC
From: Kevin Adam N9IWW
Topic: 2938 Message: 2977

Here is the demensions you need from fellow ham

These are the Tubing dimensions I used that work out. They are from Max-Gain Systems, but only buy the 8 foot lengths, UPS will be considerable more, but the length and sizes work.
Qty. Size Length
6 3/4" 8 feet Tubing
3 1" 8 feet Tubing
1 1 1/4" 8 feet Tubing
1 1/2" 8 feet Tubing
Cut the 1 1/4" Tubing to make 6 pieces to go on your Hex base plate wirh U-Bolts and add the other sizes accordingly. By the way I used
1 1/4" U-Bolts and had to stretch them a little over a piece of barstock to fit over the Fiberglass Tubing. Only use the 1/2" tubing cut in 6 pieces if you need a little more curve at the end, it isn't necessary, some people like it better.
Wire I used was 14 Gauge Flex Weave 167 strand from Rf Davis, a little pricey but excellent wire for the project.
Band Driven Length Reflector Length End Spacings
20M 219" 222" 5" & 7"
17M 169" 172" 3.5" & 5.5"
15M 145" 148" 3.25" & 4.75"
12M 122" 124" 2.5" & 4.25"
10M 109" 111" 2.25" & 3.5"
These are usually within a couple of inches in being tuned correctly.

Mast Spacing (Approx.) From SO239
20M 1.25" 17M 17.625" 15M 22.625" 12M 27.88" 10M 30.25"
The bottom of the center section is wherever the 10M lines look straight. Go up from the with each to find all band straight rather than the mast spacing dimensions, they are close but may vary a little. Even if they are not straight the antenna still should work OK most of the time. Note the wire dimensions are for one leg side only, so you will need two of each of these cut. The Aluminum Hex plate I made was 12" and 5/16" thick, but 1/4" and 9.5" across the flats is good also. By the way you tip spacing at the top will be around 113" for 20 Meters wire. Now maybe this will give a few builders better insight. If anyone would like it I can tell you how to do the center pole and Feed connections too. Jerry Farek N5GND check out my photo section (N5GND)

2978. Re: [hex-beam] Re: Ordered new spreaders from Max-Gain

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-01-12 19:51:45 UTC
From: Harold Burton
Topic: 2938 Message: 2978

The bent depth of my fiberglass spreaders is approx 30". That would probably give sufficent vertical depth to allow for a multiband Hexbeam. I can't say that for certain, though, since mine was built monoband. Dave Billheimer, W1GQL, has a internet site dedicated to homebrew Hexbeams. His url is http://midcoast.com/~w1gql/hex/buildyour.htm I, and another local Ham used info from Daves site to build our Hexbeams and they do seem to work OK. I've been thinking I'd add at least a 17 meter set of elements to my 20 meter antenna, but I've not yet done it. You might visit W1GQLs website and see what you can find. He has got something to say onsite regarding makling decisions about multiband Hexes. Visit him, I think you'll enjoy it.

Robin, I forgot to mention in my last message that W1GQL is a New Englander also.You two may be close enough to make for easy communication. Now that I think of it, Dave recently told me that his local AgWay store stocked fiberglass fence posts in a good size, 1/2" by 72 ". My local farm stores only stocked 3/8" by 48" posts, which complicated my construction.. Overlapping the 6 foot posts and using worm gear hose clamps to join them would probably give you plenty of spreader length. The electric fence posts are simply smooth fiberglass rods with a slightly sharpened end. I imagine those 1/2 inch diameter posts could carry a good deal of ice and snow, too.

Topic: 2981 Message: 2982

Hi
When I was talking to Mr Traffie regarding it, he helt it was doable, but the swr was an issue...not sure if was a match problem...but I wnted to use it instead of 10 meters..and custom build it. I don't see what it could not be done??

Hi Leo

Jan (PA2JJB)added a seperately fed 6m element to a 5 band hex with good results.
The pics are in the photo section and some details are in message #2301

Home brew..a single band would be pretty easy. As the size alone will make it managable.
..or M. Traffie does sel one too.

Unless your property is under 1.6M wide or you are installing it in
your attic then use a 3 (or more) ele yagi.
A 3 ele yagi will have more gain and better rejection off of the back
than a mono band hexbeam.

Hi Darren
What you say is very true but from the economics point of view or perhaps as a temporary measure to get on 6m with a half decent antenna it`s is only going to cost ..well almost nothing if you already have the 5 band spreaders in place.

The mast and rotator won`t even notice it, and more importantly perhaps, neither will the neighbours :)

2990. Hex Beam Height

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-01-20 02:05:23 UTC
From: ki4jwy
Topic: 2990 Message: 2990

I have a 70 foot tower that is the only place I can mount my 5 band hex beam. That would be 50 foot over my house and my metal shop building. Would the performance suffer at that height?

John

2992. My Hexbeam SWR

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-01-22 10:19:55 UTC
From: Darren G0TSM
Topic: 2992 Message: 2992

Hi All,
I've put up some pictures of the display from my quadra amp and you can see the SWR curves on my homebrew 5 band Hexbeam. The SWR isn't perfect but when I had perfect SWR on 5 bands the performance was terrible.

Darren:

In support of your point, it is worth noting that SWR affects mainly the amount of power that gets transmitted to the antenna system; not the radiation pattern or effectiveness. When you do the numbers, the difference between an SWR of 3:1 vs 1:1 in terms of power loss is less than one dB.

73,
Leo, K4KIO

Those a real good SWR plots except for 10m your covering the whole band with less than 2:1. For 10m its most of the band. No traps to eat power as in a traditional Yagi so in the end you may come out ahead with a hex.

73,
Mark N3GNW

Hi to all,

Just wondering what the dimensions for a tri band hex for 20,15,10m would be.

Should I use the dimensions for the 5 band version minus the bands I do not need ?

I cannot see anything in the files

Thanks

Stu VK2MIC Australia

2997. Making progress on MkII version

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-01-30 18:07:34 UTC
From: Mark
Topic: 2997 Message: 2997

I have been making progress on a MkII version of my beam. Over the weekend, I completed a new center mast with interal feed (Holger is right, it is a labor of love)and a new base plate. The rest should go together Friday since I have off from work.

No pictures yet, but they will be coming.

2998. Dimensions for six meters on a multiband hexbeam

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-02-01 14:32:18 UTC
From: buysmart2002
Topic: 2998 Message: 2998

Does anyone have the lengths and spaces for six meter elements that could be added to a five band hexbeam?

Thanks.

Leo, K4KIO

3000. HXB5i #413

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-02-05 08:54:08 UTC
From: David Lear
Topic: 3000 Message: 3000

A week ago I assembled and raised HXB5i #413 (with some help) and have made a photo album of the happenings, including SWR plots. It was assembled in a fairly unusual position (see photos). It is at 29ft in an antenna restricted area, with the arms painted gray, You can see I have taken some NVIS liberties, with the view from the front of the house. It is also installed over some attic mounted gas furnaces and the resulting SWR curves show the variation in the beam heading vs. SWR. My K2 ATU easily matches the worst SWR conditions.

One of the first contacts was EA8AX who was also operating a Hex Beam. Since then made several European QSOs at 100W on 15 and 17M, so it seems to working OK. Worked about 30 QSOs in FYBO on Saturday from the house, within a couple of hours operating.

3003. Six Band Hexbeam

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-02-09 15:22:13 UTC
From: buysmart2002
Topic: 3003 Message: 3003

I just finished adding six meters to my previously 5 band hexbeam. The SWR was pretty flat but lower at the high end of the band. I don't plan to try to correct this as the tuner will take care of it anyway.

I am using the same feedline for all bands and it is connected at the ten meter elements (previously the bottom). Six meters created no noticeable effects on the other bands. No baluns or toroids.

My web site has been updated for the new addition, including SWR figures at www.leoshoemaker.com/hexbeambyk4kio/general.html

From: max_ve3tmt
Topic: 3005 Message: 3005

Hi all to the group,

After considering a homebrew quad, I have decided to go with a hexbeam due to the size and weight differences. I have been researching on the net and see lots of good articles on homebrewing but am confused about the actual wiring of the hexbeam. Is the element wire just strung around the perimeter of the supports? Can someone please explain the basic operation principple and construction to me. Sorry for the dumb questions, but I am racking my brain with this.

Max VE3TMT

From: max_ve3tmt
Topic: 3005 Message: 3006

After doing more research, and an excellent on-line article by K4KIO, I answered my own questions.

1. I am only going to be able to put the beam up 20-25 feet at the most. Will this be high enough for satifactory results? Current antenna is an R7, which work great, but I want something with directivity to help in certain areas.

2. I am still deciding over a single band 20m or 20,17,15 and 10m multiband. Will I be able to feed all driven elements with one coax feed and have good results?

I apologize for all the questions, this is my project in the works and I plan on hitting the ground running come spring!

Thanks,

Max VE3TMT

Maybe I can convince you to build the 5 band version..

Here's a file, first you hear W2MAT on an R8 vertical, then switched
to my homebrew 5 band Hexbeam and then back to the vertical. I had to
edit out a few ms of the file as there was a short gap while cycling
through the antennae, but it was only a few ms. file size 79K.

As an example of HexBeam extremes I recently saw a photo of a man wearing a hard hat with a short PVC mast with a 2 meter hexbeam mounted on top of it. Rotation was accomplished by simply turning his head or entire body.

Aside from more wire, can I feed all radiating elements with one coax line? If so I figure for a little more string of elements it won't add much more weight and I will have a real multiband antenna. I have listened to some comparisons elsewhere and the difference is amazing. I would love to hear a VU2 or the VK's nice and loud but on the vertical no way!!!

I have now built two five band versions. The five'r is definitely more work esspecially if you build the center mast with internal feed. But you do have directivity on all 5 bands. If the coming snow doesn't stop me this one will be going up on 20 feet of light tower this weekend.

The first version was on a 20 foot mast with its base plate around 23 feet. Not perfect but it performed quite well in CQ WW CW. Definitely broke pile-ups a lot easier and gave me 2 S-units over my R7 vertical.

3013. What's the best way to wire up the spreaders?

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-02-10 22:05:02 UTC
From: Mark
Topic: 3013 Message: 3013

I've got my second version built and out on the picnic table. The fiberglass spreaders are a lot better than PVC but the two end ones (where the director and reflector wires come together) bow toward the driven side. A couple of the others have slight S shapes to them.

In both antennas I started wiring from 20m. would I get better shape by 10m then 12m, ...?

What other tips are there for assembling this area?

Mark,

you might want to use nylon twine to achieve the right shape before stringing the wires on. Use twelve pieces exactly the same length about 9 1/2 feet each.

String six lines around the perimeter and six radials from end of spreaders to the center. This will keep the whole thing in the right shape while you install the wires. Then later, if the wires provide the tension on the spreaders, you can remove the twine.

This approach I used is described at www.leoshoemaker.com/k4kio.html

Leo, K4KIO

3015. Its up and working

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-02-13 14:13:22 UTC
From: Mark
Topic: 3015 Message: 3015

The MkII version is up and working! (Sorry no PIX yet, priority was getting it up.) I put together 20 of the 30 feet of old Rohn 6 light weight tower I picked up, hooked everything together and my neighbor who had just came home from Florida rushed over to give me a hand and erect it as snow started to fall. Perfect antenna weather. At first SWR was through the roof on 15-20. After racking my brain I realized the PL-259's and barrel connector had been wet with snow. Even though I blew the worst of it off there was probably some water left. After the snow ended Sunday (about 14 inches - 35 cm) I took my heat gun out disassembled the connection, dried it off and voila! 1:1 to 1.5:1 accross ALL bands.

Unfortunately the plywood base plate (0.5 inch thick) is starting to wasrp from the tension of the spreaders. I'm going to need to look into metal or the cutting board K4KIO used.

First contact 3Y0X. I'm happy!

The MkII version is up and working! (Sorry no PIX yet, priority was getting it up.) I put together 20 of the 30 feet of old Rohn 6 light weight tower I picked up, hooked everything together and my neighbor who had just came home from Florida rushed over to give me a hand and erect it as snow started to fall. Perfect antenna weather. At first SWR was through the roof on 15-20. After racking my brain I realized the PL-259's and barrel connector had been wet with snow. Even though I blew the worst of it off there was probably some water left. After the snow ended Sunday (about 14 inches - 35 cm) I took my heat gun out disassembled the connection, dried it off and voila! 1:1 to 1.5:1 accross ALL bands.

Unfortunately the plywood base plate (0.5 inch thick) is starting to wasrp from the tension of the spreaders. I'm going to need to look into metal or the cutting board K4KIO used.

3019. Thoughts on PVC as spreaders

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-02-13 20:02:58 UTC
From: max_ve3tmt
Topic: 3019 Message: 3019

The local Home Depot sells 10 foot lengths of 1/2" PVC conduit for $3.49 each. It seems to flex pretty good and no doubt with the right nylon reinforcing cord I would think it would hold fine. Any reasons why not to use this material for spreaders? The length is ideal, I can put 1/2" dowel inside for clamping to the hub. I have begun sourcing parts for my first hex beam.

Max,

My first version used PVC electrical conduit. You really need to put 8 feet of 1/2 inch wood dowels to give it some reasonable stiffness. Holger DL7IO notes that at high power levels the PVC tends to soften even more. Others have noted the same problem in warm weather. (I max out around 600W and my first version was only used in cool weather.)

If I had to resurrect this version, I would place the base plate on the ground and lay out the PVC spreaders straight from the p;ate and then tie the ends and mid-points of the spreaders toghether to define the initial shape.

Pictures of my first version can be found in the photo section here.

The second version is using fiberglass spreaders.

Take a look in your local farm and ranch stores and see what they've got
in the way of
fiberglass electric fence posts. Here in southern Oklahoma these stores
stock just 3/8"
by 48" fiberglass rods for such use. Dave Billheimer in New England
found the AgWay (believe that's the name) stores had 1/2" by 72"
fiberglass rod fence posts. If your local stores have either size you
can find a way to make them work. Wish I coulda got the larger ones, but
I made do with the 3/8" by 48" posts when I built my Hexbeam.

Thanks for all the insight and ideas guys. Looks like PVC, although cheap, isn't the best way to go. In my city, farming is not big, but I will look around the local Co-op store and see if they have fence posts. Walmart or one of the other sports stores may have the fishing poles but I really wasn't hoping to spend that much seeing as it is my first hexbeam.

well i have used pvc for a 10 meter 2 element quad i made . it did pretty
good . but at that length it tended to sag . it did real well for a 2 meter
, 8 element quad . it just tends to sag with too much length and or wieght .
you could use dowel rod to strangthen it but then again why not just use
dowel ?? jL kd5dfm

The 3/8" by 4 foot posts are 99 cents each here in the Red River valley. The 1/2" by 6 footers are probably about $3 (if I could find them). They'll be both cheaper and stronger than fishing rods. A dozen of these larger posts cost about $30 ordered on the net, but shipping runs above $50. That's why you've got to find a local source, the shipping costs are horrendous. All you can do is shop the local farm/ranch stores and hope you're lucky.

Hi Larry,
Once you have the experience of homebrewing a five band hex complete
with that associated 60 mile hike round and round the antenna :)

It should be possible to build a monobander from scratch in under 3
hours if you have all the tools and materials to hand.
For a 5 bander you would need at least a long weekend ;)

The first version took a little over two complete weekends. The second version about the same. While I didn't have to re-cut the wire I did build an internal feed mast. Holger is right, its a labor of love!

At one point I had to disassemble the internal feed to fix a broken solder connection. The trick I learned there which made reassembling a lot easier, was to drill 1/4 inch holes for the 8-32 screws I used. I put an extra washer on the screws before re-inserting the feed line. This gives more bearing surface so the screw heads don't work there way out. I need to add a little sealent around all these holes since they are now much larger than the screw.

Hi Mark,
I can sympathise with you on that internal feed.
My solution was to drill holes in a 2"x1" timber that match the post
hole locations.
I put 5 brass bolts into the timber and soldered the heavy copper
feed to the bolt heads.
You then fish the entire "string" down the post and turn it ,as long
as you line up the top bolt,the rest will miraculously appear through
the slightly oversized holes with a little gentle shaking of the post.

Worked well for me :)

Here is a thought..and you know what a thought made man do..LOL

I was thinking... is it possible to phase 2 beams at 40' then stacked at let's say at 90' for a total of 4 beams in play???

you would place 2 beams phased together a 40' on a tic ring then stacked at 90' on a ring. Both phased arrays able to rotate...

am thinking of things to better what I have for things to do as wx gets better..

3032. 6 Band Hex Beam - Wind Loading Study?

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-02-15 20:36:45 UTC
From: Dave Willey
Topic: 3032 Message: 3032

I know the 6 band (6-20M) hex beam is lightweight, but has anyone done a model study on wind loading? (For myself I'm thinking of the telescoping 10' B'n'M "Black Widow" (BW4) poles & 16GA stranded flex wire.)

I bring this up as I'm looking for a small rotor to match a hex beam I'm currently building. The tower that I'm thinking of installing it on is a shared resource & the owner is pushing the limit with his commercial customers as it stands. He wants specifics for both the rotor and the antenna before he'll give me the O.K. to test install antenna/rotor/radio/computer it to see if it "plays nice" with everyone else that's at the site now..

Like I said.at the top, I wouldn't think it would be much. But he wants some sort of harder evidence beyond a "warm fuzzy guestamation" on my part.

Hi Holger,

I'm in process of building a homebrew 6 bander hex beam (6-20M).

I've dug around enough in the files/link sections to
have gathered up both your instructional .PDF off your webpage,
and d/l'ed v3 of your excellent spreadsheet off this list.

Being a big fan of Excel, I added several features
to your v3 spreadsheet, as well as having come up with some
other suggestion for newbies like me to tie the bits of web
information together into one resource package.

Can you email me off the list to discuss these add ons &
suggestions?

My e-mail address is good on QRZ.com.

Thanks,

Dave - N6DSW

Thanks Allen,

Home Depot has the gray conduit. I think I will go that route and put dowel in the tube as suggested. It should be pretty hard to see against the sky as well. I was at Walmart last night and they have 10 1/2' crappie poles but at $67 each I think I will go the PVC route.

I have got lots of great advice from the group and cant wait to get started.

Max

3036. Hexbeam crappie poles for under $12

3037. Re: 6 Band Hex Beam - Wind Loading Study?

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-02-16 15:51:28 UTC
From: Colin
Topic: 3032 Message: 3037

Hi Dave,

I shouldn`t think it`ll be much over 2 - 2.5 sq ft, if that.

I use a old (ancient hi) medium duty emotator rotator on mine and
it`s more than powerful enough.
A channel master tv type rotator would probably cope well.

Cabela's has the 13' model for US$11.83 each.
Plus no tax for Calif. residence. (YEAH!!)
Standard shipping.

http://www.cabelas.com

Search term: "B'n'M Black Widow".

Mine are due to be delivered the 21st.

(And the usual disclaimer here...)

Ha! I just checked Cabela's website again after I sent the previous post.
1 page says 11.83. Another page says $9.99.

I called Cabela's just now & it is indeed $9.99 each for the 13' model
Cabela's Item number: IG-110503..

If you can find a local fishing tackle dealer on ebay,they usually have seconds (broken top eyelets,bottom bungs missing etc) which makes them non-saleable for fishing but still fine for hexbeam spreaders.

I bought a mixture of 6m and 8m rods for antenna experiments, 18 in total for £56 incl shipping.

Might be worth a try.

Dave, why don't you use the figures for the Mike Traffie commercial version; I doubt there would be much difference.

73, Leo, k4kio

Dave Willey <davewilley@...> wrote: I know the 6 band (6-20M) hex beam is lightweight, but has anyone done
a model study on wind loading? (For myself I'm thinking of the telescoping
10' B'n'M "Black Widow" (BW4) poles & 16GA stranded flex wire.)

I bring this up as I'm looking for a small rotor to match a hex beam I'm currently building. The tower that I'm thinking of installing it on is a shared resource & the owner is pushing the limit with his commercial customers as it stands. He wants specifics for both the rotor and the antenna before he'll give me the O.K. to test install antenna/rotor/radio/computer it to see if it "plays nice" with everyone else that's at the site now..

Like I said.at the top, I wouldn't think it would be much. But he wants some sort of harder evidence beyond a "warm fuzzy guestamation" on my part.

Dave - N6DSW

From: dl7io
Topic: 3032 Message: 3044

Hello Dave and folks,
let's see if we can bring some light into this.

The windload is described as F=q*a, where
F = windload in N
q = impact pressure in N/sqm or may dynamic pressure (not sure what the correct English vocabular is) and
a = antenna area in sqm

Of course you can use sqft instead of sqm.

The area of your antenna you have to find out yourself by calculating/measuring your own design. But please remember that there are 2 approaches.
No. 1 looking from top onto the antenna and use this seen area.
No. 2 looking from the side and use this seen area.
For our antenna usually the from the top seen area is bigger (baseplate, all spreaders and wires are seen from top).

If you use round materials (tubes) instead of square materials, you can use the factor 2/3 to reduce the area because the wind resistance of a tube element is of course smaller than for a square element.
I propose to leave this factor as a security factor and don't bring this into your calculation.

Regarding the impact pressure q we in Germany use following values.
(I'm pretty sure if we Germans accept those values you can use this for your case as well)

q = 800 N/Sqm for max. wind speed of about 120 km/h (to be used if antenna height is smaller than 20m)
q = 1100 N/sqm for 140 km/h (has to be used if antennas are 20m or higher)
q = 1600 N/sqm for 160 km/h (has to be used in high wind areas, like mountain or coast locations)

to change km to miles remember 1 mile= 1,6 km, e.g. 160 km/h = 100 miles/h

What you saw already is that doubling the wind speed means 4 times more windload for your infrastructure (tower & rotor).

You can go on Andrews web site and download there
Power tools software and let it calculate wind load
and just about anyothe parameter. I use this to help
engineer microwave sites. then I look for equivelents
and I use Pathloss for actual Path calc's. They have
some good free software.

Thanks Allen,

Home Depot has the gray conduit. I think I will go that route and put
dowel in the tube as suggested. It should be pretty hard to see against
the sky as well. I was at Walmart last night and they have 10 1/2'
crappie poles but at $67 each I think I will go the PVC route.

I have got lots of great advice from the group and cant wait to get
started.

3047. Crappie poles too thin?

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-02-19 16:30:22 UTC
From: buysmart2002
Topic: 3019 Message: 3047

If you try to use a ten foot crappie pole for 20 meters, indeed, the last section is too thin. The key to using the crappie poles is to buy the 13 foot version but use only the first three sections. This way, the last section is 1/4 inch thick at the end and adequate for a six band hexbeam.

Seems to work great for me; I suspect the failures of others have been use of the smaller 10 foot pole which would give you an end section much too thin to do the job.

73,

Leo, k4kio

3048. Re: [hex-beam] Crappie poles too thin?

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-02-19 17:03:43 UTC
From: Harold Burton
Topic: 3019 Message: 3048

When I used 3/8" by 48" fiberglass electric fence posts (round fiberglass rods) to build my 20 meter monoband Hexbeam I complained to W1GQL, Dave, (whose internet site I used for element dimensional info) that our local farm and ranch stores didn't stock larger sizes. Out of curiosity he checked his local Agway (think that's the name) and found that they stocked 1/2" by 72 inch posts.Using those would make for a slightly heavier antenna, but much, much stronger than any of the "drappie" poles or my smaller fiberglass posts. I only wish our "Orschelns" and "Tractor Supply" stores would stock the half inch by 6 foot posts. I was able to utilize the 4 foot 3/8" posts but it did require some ingenuity and a heavier "extended" hub.

yes, that's exactly l what I did ...I used 10 crappie poles for a 20-meter antenna and they were too thin and broke.....

Seems to work great for me; I suspect the failures of others have been use of the smaller 10 foot pole which would give you an end section much too thin to do the job.

gerry nunan <ke5dwm@...> wrote: Max ...

hate to discourage you, but i tried both crappie poles and 3/4 inch PVC .... both were a dismal failure ... the crappie poles tapered too much and started to break before i got it up in the air ... went to 3/4 inch PVC and two things happened: 1) they sagged badly after about a month in the hot sun 2) the thing weighted 27 lbs when i got done .. (although it worked very well .... got thru Field Day with it) ... finally bought a 20 meter lightweight from Mike Traffie and it's great ... he has engineered around all the problems I had .. and the antenna weights 7 lbs (not 27 lbs) ..... it's a hot little pistol and i can turn it with an old AR-22 rotator ...

good luck .. regards ... Gerry ... K2HIT (ex, KE5DWM) .. near San Antonio, Texas

Thanks Allen,

Home Depot has the gray conduit. I think I will go that route and put
dowel in the tube as suggested. It should be pretty hard to see against
the sky as well. I was at Walmart last night and they have 10 1/2'
crappie poles but at $67 each I think I will go the PVC route.

I have got lots of great advice from the group and cant wait to get
started.

Max

Would probably have to be 80 feet in diameter, Might get a bit clumsy to
hang and rotate.
Mind you thats just a guess, I didn't try to work it out to find the
dimensions. My 20 meter monoband is 20 feet in diameter. I don't think
I've heard of anyone trying anything larger than 40 meters.

From: Dave Willey
Topic: 3051 Message: 3053

Just for yucks, I used the spreadsheet that is in the file section in the Hex Beam discussion area..

I just scaled down the freq. & let Excel compute using the stock formulas. (Freq shown is the center portion of the US General phone band)

And the results are:

80 meters
Center freq: 3.925 Mhz
Driven Element Length: 131.21 feet
Reflector Length: 133.38 feet
Driven Element Spacing: 2.17 feet
Reflector Spacing: 1.38 feet
Over All Element Spacing: 3.08 feet
Spreader Length:32.80 feet

And for those folks who are REALLY reality challenged...

160 meters
Center freq:1.900 Mhz
Driven Element Length: 271.05 feet
Reflector Length: 275.53 feet
Driven Element Spacing: 4.47 feet
Reflector Spacing: 2.85 feet
Over All Element Spacing: 6.36 feet
Spreader Length: 67.76 feet

Of course your mileage may vary

Ya think B'n'M got crappie fishing poles that size?
(Don't forget that you'll need to order longer poles since you don't use the last 1/4 of the poles. They are too thin....)

hey ive seen 80 meter beams lol ;-) monsters , the longest element on my mosley tribander is 29 ft . So 32 feet isnt that far off . god know what you'd use as a spreader though . i am thinking of a warc band hex ;-) that would be neat . i would think a fourty meter hex would be hard to do even . id like to see one . maybe you could find a tree sufficant enought for the stationary 160 hex lol ;-)

3055. Re: 80 meter monoband hex

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-02-23 14:44:52 UTC
From: dl7io
Topic: 3051 Message: 3055

Hello Tom,
Don't use the formula out of the mentioned excel spreedsheet.
Nobody has calculated and built more mono- and multiband versions starting from 40m than I did and the formulas are not useful for the lower bands. But my calculations with EZNEC matched very good for all the different 40m versions. That's why I'm hopeful that the 80m dimensions are also correct or very close
Wire used for calculation is not insulated 1.5mm². The diameter is not critical. I would recommend to use bigger diameter to get better bandwith. If you go for insulated wire the elements will be shorter by 3-8% depending on the islotaion material and thickness.

If you will go for a 80m monoband version try the following dimensions:
radiator leg (half radiator): 22,00m
reflector leg (half reflector): 22,60m
tip space radiator side: 50cm
tip space reflector side: 42cm
spreader length needed is 12m.
1in=2.54cm

But remember that the antenna should be installed about 30-40m high. Otherwise you will have a very high TOA (to high for serious DXing) and a 1/4 wave vertical would be the better and cheaper choise.

73 Holger

PS. I have published monoband dimensions for 6-80m on the first sheet of the excel file I published to get the XYZ coordinates needed for any antenna calculation software out of changing tips or element dimensions of the folded hexbeam elements.

From: ion_moldovan
Topic: 3060 Message: 3060

I am looking to purchase these rods. Did anybody used this kind and can tell me if they will work?? I am planning to build the 5 band hex 10, 12, 15, 17 and 20. These rods are 16 ft long each and the price for 6 of them is about 50 bucks. I figured that if I get the 16 ft long ones i can chop them to the right length and be a little stronger than the 12ft long ones.
Thank you...

Roland, I haven't thought a lot about this but it strikes me that a 2 meter hexbeam wouldn't be such a hot idea. The main advantage of a hexbeam is getting a directional 2 element antenna that is physically small with reasonable performance.

At two meters, it would just about make more sense to me to just build a Yagi, 3 or 5 elements since it would still be small and give a lot better performance. But I am not an expert on two meters.

73,

Leo, K4KIO

Just for fun , yes build away!...Honestly it would work fine but it would be much better as previously stated to simply build a yagi or quad for 2 meters or shorter wavelengths...The hex is a compromise affair that works fine..It is basically a way to get a low profile, small foorprint HF antenna..at a cheap cost(unless you buy it from traffie of course). If you want to build one six meters might be a better spot to experiment! It won't be a big antenna for at that frequency but you could learn the basics and have something useful to show for it!....W4HV

Try using an umbrella for a frame and that real thin
coax. It would be great for a handheld and easy to
fold up. PS probably have a hard time finding an
umbrella without metal soreaders.

Topic: 3065 Message: 3067

Riann,
Can you please share all dimensions and a diagram if you have one?
How did you calculate the dimensions?
I'm very interested in a 40 meter version.

Tom

Hi all
I am in the process of building a 6-band hex-beam. With 40 m added the spreaders are about 6m long and the antenna is a bit bigger than the 5-band Hex-beam.

That would be about as wide as my house! The XYL would love it.

Hello,
a couple of different 40m designs can be found on my webpage.
www.hexbeam.de
They come with EZNEC files and pdf's with results and dimensions.
I have built all of them already.

3071. Does anyone actually have an HB mounted in their attic????

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-03-09 22:56:50 UTC
From: Johnne Ables
Topic: 3071 Message: 3071

Because of CCRs I am limited to an attic mounted antenna and a Force 12 Flagpole vertical with radials. My license expired 25 years ago and I am retaking the test within the next month or so. I always believed that if it sounds too good to be true it probably is. I like what I've heard about the HB, but I don't want to spend a Grand unless I can have some assurance of perfomance.

Anyone?

thanks,

Johnne

I've got a 21+28MHz version in my attic, it's actually mounted upside down, it's a pair of mono banders using separate feed lines. I haven't ever worked/heard anyone on it as the noise from the computers, electrical appliances etc makes hearing anything impossible. I thought about covering the attic floor with aluminium foil but never got round to it. It was going to be part of my mini-contest station that i started to put together, the idea being that the Tx ants were down the garden 140ft away and the Rx ants were at the house, so in theory I could run SO2R or have a 2nd op in, quite a good idea at the time. The only other problem was that 20M wouldn't fit in the attic...

You could always completely cover the attic floor with copper mesh and then use 1/4-wave Ls or Ts for 10M~20M or maybe 30M. That would work, and would be cheaper :-)

Welcome back to ham radio !

All I can say, is bang for the buck, the home brewed antennas all seem to be making contacts.
I have a Traffie, and it is great. I am sure I could do a little better with a full size beam. But I have no room. The hex has served ne very well on all 5 bands. It has broken many a 15 -17-20 meter pile up, with only 500 watts.
Very effective antenna...again for it's size. Not cheap, unless you home brew.
But is flat out works !!

Actually, with a bit of research and some judicious shopping, you can build your own
for a mere fraction of what the commercially produced Hexbeam antenna will cost. I built a 20 meter monobander for under $60 using fiberglass electric fence posts, nylon cord and solid 14# copper wire (I utilized my scavenging skills to obtain free 5/8" thick HDPE plastic
for the hub and a 4 foot length of fiberglass thickwalled tubing for the central shaft.). The two links below will give you considerable do it yourself info on the Hexbeam. All the dimensional info I used in building my Hexbeam came from W1GQLs website. I helped another local Ham build one and then built my own.

Johnne,
I homebrew a hex beam for 20-17-15 meters. I work peter 1 island which is located 350 miles west of anarticia 2 weeks ago on 20 and 17 meters running 100 watts and it only took 5 calls to break the pile-up. No brag just fact as an actor use to say.

In your attic you could string up some wire pionted in
a good direction and give it a shot without all the
hassles of rotater and spredders. make a few calls
and see if it would work.

Harold,
I found some fiberglass poles at one of our local ag stores. Its a 5
foot pole 1/2" diameter for a little over $2.50. They are pretty
stiff. I would like to see or have you describe how you made adapters
to join two of these together. I looked in the photos section. I
seem to remember you describing it in a previous post, but I couldn't
find it.

Yessir! Sounds like you've found some good spreader material. I'd have loved to have been able to get the 1/2" by 5 foot posts you describe. Our local Southern Oklahoma farm/ranch stores only stock 3/8" by four foot posts. I made those work by being lucky, a local Ham gave me a fairly large piece of 5/8" thick HDPE (high density polyetheline) plastic sheet. I cut this into 1" wide strips 6" long, drilled lengthwise holes to fit my posts and assembled posts and plastic strips like Tinkertoys (only with glue). This, along with some creative hub work, allowed me to get the length I needed for my 20 meter monoband spreaders (roughly 10 feet). To do the same thing with your 1/2" posts you might need some 3/4" thick plastic sheet (HDPE, Acrylic, or Polycarbonate would probably work). By the way, I should warn that trying to drill strightthru holes in the plastic strips was not a simple task. You might also be able to achieve what ever length you need by simply overlapping the posts and clamping them with wormgear stainless steel hose clamps. With a one foot overlap between posts and four clamps you can probably assemble 3 posts into a spreader of up to approximately 13 foot length. This should give you as much length as neccessary, depending on the Hexbeam configuration you seek to build. I would have attempted to build mine in this manner had I been able to get the larger posts. Let me know if you wish me to try to directly send you photos of my Hexbeam and I'll give it a try. I don't want to attempt to send them thru the Yahoo Group because it might result in my electronic lynching.

Harold,
I originally bought them to make a 6 meter hexbeam, but decided it's too stiff. I know I don't have to have the bow for a single band hex, but decided maybe I'll make a 2 element quad instead for 6 meters.
I have a lake home and would love to put a hex up there. I have a commercial hex (got a heck of a deal new from Burghardt's) at home, and would like to have a decent antenna at the lake home!
I think I exagerated the diameter. I laid a pole on a ruler, and it is probably closer to 3/8". Still plenty stiff though. Thanks for the ideas about a connector. I like the idea about the 1 foot overlap and SS hose clamps. Both give me food for thought. Keep the good ideas coming Harold!

"I have a
commercial hex (got a heck of a deal new from Burghardt's)"

Did you buy a Hex Beam from Burghardt's? Please explain, I didn't think they sold Hex beams.

Subject: [hex-beam] Now fiberglass fence posts

Harold,
I originally bought them to make a 6 meter hexbeam, but decided it's too stiff. I know I don't have to have the bow for a single band hex, but decided maybe I'll make a 2 element quad instead for 6 meters.
I have a lake home and would love to put a hex up there. I have a commercial hex (got a heck of a deal new from Burghardt's) at home, and would like to have a decent antenna at the lake home!
I think I exagerated the diameter. I laid a pole on a ruler, and it is probably closer to 3/8". Still plenty stiff though. Thanks for the ideas about a connector. I like the idea about the 1 foot overlap and SS hose clamps. Both give me food for thought. Keep the good ideas coming Harold!
73,
Terry, WK0F

I bought it a few years ago. I think it was a demo. I'm sure they
don't carry them anymore. Mine is #250.

Go to www.yahoogroups.com and join the HexBeam reflector group. You will not regret it and you will get all the afffirmation you desire on this outstanding antenna. The only thing better is the Fluidmotion SteppIr yagi beam, but it is much larger and cost a lot more. Have one. If not, It would be the hexbeam.

Subject: [hex-beam] Does anyone actually have an HB mounted in their attic????

Because of CCRs I am limited to an attic mounted antenna and a Force 12 Flagpole vertical with radials. My license expired 25 years ago and I am retaking the test within the next month or so. I always believed that if it sounds too good to be true it probably is. I like what I've heard about the HB, but I don't want to spend a Grand unless I can have some assurance of perfomance.

Anyone?

thanks,

Johnne

Dear OM,
The only comment I can tell you is from my own experience with the HexBeam. I had a 2 element Lightning Bolt antenna up at 45 ft on a crank up tower for 2.5 years. For the last year and a half, I've been using the Hexbeam by Traffie on the same tower and feedline as with the quad. I've found no difference b/w it the the Lightning Bolt in all aspect.
The only down side is that it is three times the cost of the Lightning Bolt, but the upside is that it has NO windload resistance, very easy to put together and practically maintenance free. On top of that, I'm using a Radio Shack rotor to turn the antenna and it works great! Sold the Ham IV that used to turn the quad.
Esthetically, it is not as obstrusive as the quad. The neighbors think that it is some sort of a satellite antenna. I tell them that it is a "Hi-Def" antenna for my big screen. It works...

3088. SWR, gain and F/B ratio + hi. I'm new here!

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-03-14 23:55:50 UTC
From: Pete Millis
Topic: 3088 Message: 3088

Hi folks. I'm new here, and am in the middle of some experimentation. Currently using a vertical Moxon rectangle on the beach (see http://www.moxonantennaproject.com/m3kxz/M3KXZ_VERTICAL.htm) Another ham put into my head the idea of turning my Moxon into a diamond shape so I could use just one support pole. Fiddled with this in EZNEC for a while but it seemed to be lacking too much in gain and FB ratio compared with my Moxon. So I then started toying with the idea of the Hex Beam, but close to the beach (i.e. 1/2 metre above salt water ground) and in vertical orientation instead of horizontal. I've come up with a design that gives over 10dBi gain and over 32dB F/B ratio at 14.2 MHz which compares well with my Moxon (ez files available on request) but I have a question about the SWR and the change in gain and F/B across the band.
The question is this....
When I model the antenna, I get a much higher gain and F/B ratio at a frequency some 200 to 300kHz BELOW the point of SWR minimum. If I set the antenna up to obtain minimum SWR acorss the band then the gain drops by a couple of dBi and the F/B ratio becomes very poor. Is this something that is normally observed? With my Moxon, best performance is at a frequency higher than the SWR minimum frequency. I'm not bothered about SWR numbers as I believe they are generally pretty meaningless so long as they are under 3:1 and I'm happy to use a tuner anyway. Just curious that's all!

I'm building my hex Beam tomorrow and will post up some pictures in due course, along with a comparison with my Moxon.

72s, and thanks for the useful Yahoo group!

Hi Pete,

I think the Moxon will result in higher F/B than the hexbeam (as that is the nature of the beast) but the single support for the hex with a few strategically placed guyes would likely be faster to set up on the beach.

A 40m version would also be much less unweildly than the equivilent moxon too, allowing you a bit more scope for beach experiments.

Models give a idea of what to expect but i wouldn`t rely on the data too much, it`s fair to say the f/b peaks don`t coincide with minimum swr or max gain.

In practice though the hex does perform surprisingly well given its compact size.

I`m looking forward to the results of your vertical hex-periments.

Topic: 3088 Message: 3090

Hello Pete,
welcome to the group and nice to have someone else who is calculating antennas.

Your results are correct and match with mine.

Taking a given wire configuration you'll find the best gain below the area where you have a SWR of less than 1:2.
In the file of a presentation I held last year on a HAM meeting you can find a figure which shows on a 40m design the relation between gain, SWR and F/B in function of the frequency. This file is on the bottom of the data page.

The problem is, that in this area the SWR changes very much and needs to be tuned permanently like with a magnetic loop.
To get a useful optimum especially for singleband versions, I suggest to go for a 25 Ohm design like known from the reflected M or X-beam.
The frequency area where you can have a SWR of about 1:2 is about 150-200 kHz more down where the gain is better.

Make a quarter wave long stub of 37 Ohm coax (2 x 75 Ohm in parallel) to build a 1:2 unun and connect you 50 Ohm coax. Than you would not need a tuner. But the bandwith is a bit smaller than for the 50 Ohm design.

In practice it is hard to measure those values correctly. While measuring the SWR it is not rising that much as expected from the model. But if you try to have as less cable as possible you need to be in the antenna which will also influence the system. And measuring the gain is in my eyes almost impossible in the field. But you can comfirm the data for SWR and F/B which brings me to the conclusion if the theory is correct for this, than it should be as well for the gain.
You may compare the antennas trying to have similiar installations.

Nevertheless the difference in the gain is about 1-1.5 dB. And the question is: Is it worth to make this effort (stubs, matchboxes etc.)
One bad connection point or even many good ones (and you will have a few more if you use a stub/matchbox) may cost you much more gain.

In my eyes the possiblity of using the direct 50 Ohm feeding with a better bandwith has much more advantages than the effort of special feeding arrangements etc. This is mcuh more the case if you go for multiband designs.

Have success and keep is informed.

Just a quik thought based on what you guys are saying back and forth ,Holger, Have you tried using a 50 to 75 ohm balun for the feedpoint transformation? Since basically we are using a multiband fan diople (with some bending) on the multiband versions of the hex. Since dipoles are inherently 75 ohm antennas, it would seem that this could account for the difference in resonance (of the antenna) and best match VS best performance...PEOPLE DON'T KNOW THAT DIPOLES PRESENT A 1.5 TO 1 SWR TO MODERN RADIOS AT RESONACE!!!!!...Just a thought to ponder...W4HV

3092. What wire gage do I need??

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-03-18 15:04:28 UTC
From: ion_moldovan
Topic: 3092 Message: 3092

I am in the process of building the 5 band 10-20 hex beam. What gage wire can I use? According to the article it calls for 1,5 mm2 wire. What gage is that? My local store had 18 AWG bare copper wire, 7or 8 strand. Can I use that?. Thank you...

3093. Re: [hex-beam] What wire gage do I need??

By my calculations, 1.5mm2 is 38 mils and that is close to 18 gauge.

I am using 16 gauge wire but don't see any reason 18 gauge wouldn't work fine.

I have used Radio Shack Antenna wire on my hex-beam . It is a stranded wire and will bend very easily and is less expensive than the flex weave wire from Davis Products.

Check out this page:
http://www.powerstream.com/Wire_Size.htm
It has a conversion table to the most common dimension.
A=1.5mm² is a diameter of 1.38mm.

I used 14 AWG (U.S. guage) wire. Considering the tension that the spreaders can put on the wire the heavier guages may be better.

Duke and others,
I'm thinking of getting a Hustler 4BTV for 40 meters.
Thedistance and height from my Hex Beam will be within 4 ft(I need to put it in that location).
Any comments of interference/problems between the two?

I looked at thewireman website and I am thinking to order #541 wire. That is 14 AWG, 7 strand hard drawn copper. Is that OK?? At about 9 cents a foot, I think it's a pretty good deal.

I need to mount a vertical for 40M about 2-3 ft away from my hex beam. Is this going to cause RFI or impair my signal with either antenna?

BTW, the vertical will be a Hustler4BTV, anyone have any experiences with this vertical.

I have a 75-40 meter dipole about 5 feet from my hex, and slightly below...no issues on either, that I can detect.

The only thing...I had a watt meter in line with one of my two stations. If I ran the oposite rig...it would move the watt meter on the other. I guess I was pumping some RF back down the other antenna's coax ? And this rig was off !

Well I have the 5BTV which is basically the same antenna with the 80 meter add-on. Forget the 75-80 meter portion and you have a decent antenna that performs well on 40, 20, 15, 10. I have three ground radials for 80 and more for each of the higher frequencies. I regularly use mine on 40 with excellent results. It works far better then I anticipated a vertical would.

I do have problems with 15 when it rains -- swr climbs a fair amount. This phenomenon is not noticed on other bands,

What else would you like to know?

VE7AJJ,
Tnx. I will only use it on 40meters, as the hex beam is superb on the other bands.
How many 40m radials in what directions and length?
I'm resricted to only north and south directions .no east or west access.
Appreciate you comments and insights.

WA7OB

Well I have the 5BTV which is basically the same antenna with the 80
meter add-on. Forget the 75-80 meter portion and you have a decent
antenna that performs well on 40, 20, 15, 10. I have three ground
radials for 80 and more for each of the higher frequencies. I
regularly use mine on 40 with excellent results. It works far better
then I anticipated a vertical would.

I do have problems with 15 when it rains -- swr climbs a fair amount.
This phenomenon is not noticed on other bands,

What else would you like to know?

I have radials to the north east and south plus points in between. Can't remember just how many (12? - 20? something like that). No possibility of putting radials to the west. As well I have a mountain just to the west (I mean I am part ways up the mountain) so not good for propagation to the west. Good thing I am on Vancouver island, about as far west as a body can get. Hi. Like I said, at least for me, the hustler vertical works quite well on 40m. I seldom use more then 50 watts output. 73.

Had a homebrew hex for 10m, loved it, will be working on one for the other bands in the near future

Date: 2006-03-23 21:15:43 UTC
From: Garry
Topic: 3106 Message: 3116

That's it. Though for the first while I just had the 80 meter
radials and it still worked good with just them. Later I added the
others for the rest of the bands. My only complaint would be that 15
mtr coil. I took it apart but could not find the problem.

3125. Ground Fault Device

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-03-29 13:41:50 UTC
From: dk.weiss
Topic: 3125 Message: 3125

On 20 meters
IC 735
Single Band HexBeam Home Brew
No Choke
SWR 1.2:1
Antenna about 15 Feet above and 10 feet laterally displacd
from circuit wiring.
Ground Fault Breaker is opening

Anyone have a solution for me?

Dave

If it doesn't do it on say 17 or 15 m, then you likely need the RF
chock.

Your rf field may trip it still if the field intensity is high enough...I would reccomend a basic choke balun...Just wrap the center pole with 10 turns or more of you coax ...turns should touch each other. In your situation the wiring likely could pass in the wall even closer than you state the gfi location...In that case some 500v .001uf poly style caps on the ac hot and neutral to ground might help. This will not affect gfi operation...Otherwise moving the antenna so that you wiring is out of the near field wolld be the only solution....(or you could violate code and change to a regular outlet) I am assuming its a gfi outlet not a main breaker..W4HV

Ground the outer shield on the coax and run the balun.
this should keep the rf at the antenna and not radiate
from the coax.

Be careful not to penetrate the shield. Another way is
to buy a lightning arrestor and use it. Ground should
be separate from the house ground system. Drive your
self a couple of ground rods. these are typically 8
feet long then attach the ground wire. the tower or
pushup pole should also be grounded. I work in the
wireless industry and we ground everything. including
the fence. that is a commercial application.

Hi Clay, Thanks for your reply.

The breaker is back at the panel, 75 feet away. and on a
completely different circuit than the rig is on.
Must be radiation pick up on the coax.
My grounding, is P Poor, and now that I begin THINKING for a
change, I have work to do to even approach what I consider
to be an acceptable work up on grounding.
Got lazy, and that never works well.

Stay tuned, Over next few weeks will report progress in
increments.

Dave

Like others have previously reported, I suspect that RF is traveling down the coax shield. A choke balun should prevent this from happening. There is a formula for figuring out the required number of turns. for HF bands, this usually amounts to 18-21 feet of coax wound into a coil -usually on a 4"-6" form and each loop should touch the other. It should be placed as close to the feedpoint as possible. Also, lets not confuse RF grounds with safety (electrical) grounds. The Hex is basically a two element dipole (dipole + reflector) so it doesn't require an RF ground. Your station -rig, accessories, etc should all be properly grounded for safety's sake, and to prevent ground loop problems.

As for the GFI itself, it's mounted in a grounded metal enclosure (breaker panel box) and it will be properly grounded. If it's not, you've got much bigger problems ;) -Perhaps it's defective?

From: dl7io
Topic: 3139 Message: 3139

Hello, if you work some of the VU4AN/VU... than there is a good chance
to have a hexbeam on the other side as well. The Polish guys and
DL7DF/DK1BT have hexbeams I made in use.
Calls are: VU4AN/VU3RYB, ...SIE, ...NZC, ...RWN,...RYG

3140. Re: [hex-beam] Hexbeam... Cut the coax?

Hi,
The wx here in Idaho is finally getting to where I can put up the antenna...I would like a few of the toroids if the offer is still on. I will be more than happy to pay for them and the postage..Anything express to get them here in a hurry would be OK.. How many do you think it will take to do the job??
Thanks,
Ed NT4TT

Yes, I still got a few. Let me know how many you need. The large ones are $2.25 each and the small ones are $1.50 each.
The larger ones fit over 9913 type coax nicely and the smaller ones fits over the typical RG-8X type coax.

Hello Riaan,
Files-->DL7IO->ReflectedW_6m.pdf
I have done a simulation for another ZS-HAM about 1.3 years ago(see message 2295).
As I have no 6m license (limited by number and given by lottery in Germany) I have never built/tested it.

Why bother! a regular yagi is so small on six!...The
hex has no advantage here...A 3 element yagi will fit
into the same space practically and have better
performance..

Mike's point is a good one if you are thinking of a six meter monoband hexbeam. It would be more productive to just build a Yagi. But if you are building a multiband hexbeam, adding six meters to it is a piece of cake.

I did that on my multiband hexbeam and the SWR results are quite good.

K4KIO,
Can you share the inches and feet dimensions for the 6M add-on to the 5 band Hex?
Does it bring in the SSB signals well?

From: Duke - NA1A
Topic: 3148 Message: 3148

Just got in some of the very best extra heavy duty toroids usable in RFI suppressions. These are snap-on ferrite toroids. They fit very well over 9913 or RG8 type coax. Other sizes are also available.
Anyone interested e-mail me directly for picture and more infos.

Just a note to say I have the beam up...it is at 20 ft at the moment... will be up to 40 shortly..

1st station worked V73RY after 3rd call...then UN9IO 1st call...
then it goes on from there..

swr's look good across the board...however got a high swr flag on 17 off the rig...but on the swr meter it looked good...so we will see..but am happy with results so far..

hope to hear you guys on next weekend for the 7land qso party..

Hello Dick,
we have only a limited number of licenses for 6m (I guess around 7000 for 80000 HAM's) and the user status in this band is secondary as there are some TV activities already that may be influenced.

To get a license you had to apply for and the winner were taken like in a lottery out of the box. Me and my wife applied but like in the real life we never win/won in lotteries...

We take it easy as there is still enough to do with serious business, kids growing and we even have some work left on the hf bands (319 DXCC confirmed but strong defizit on the low bands 80/160m). The next maximum is far away and so we have a target for later.

Where are you located in Fiji? On Viti Levu and if so where?
We have been numerous times to Fiji since 1992 and used 3D2IO and 3D2AO (my wife Birgit, DL7IQ).

Hello Holger ..... Thanks for the explanation ! ! I
would have
thought that in DL, the old low-band TV would have been forgotten by
now.
Anyway, I live about 5km to the east of Sigatoka and have been here
for 9 years. Maybe see you one day if you come this way or maybe
contact on the bands if they revive ! ! I'm nearly always on Olivia
so
may contact you on that mode if you use it. Often worked HB/DL but
at present bands are hopeless.

Looks like Holger will get to test his 6m hexbeam :-)

Finally very good news from DL: In July the 6m band will be released
generally to all radio amateurs in DL (except novice class). So
thousands of new stations will be active on 6m from DL this summer.
Many of them had to wait 15 years for this opportunity.... 73 Joe,

3157. Re: [hex-beam] Re: 6m Hex dimensions?

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-05-11 01:10:45 UTC
From: Leo Shoemaker
Topic: 3142 Message: 3157

Terry, I have added 6 meters to my five band hexbeam and it is fed with the same coax that feeds the other bands, and at the top of the post. SWR curves look pretty good. You can see info on my hexbeam web site.

73,

Leo, K4KIO

t_ashland <t_ashland@...> wrote: I too would like to add 6 meter elements to my 5 band hex. Can I also
get the dimensions? Did you feed it separately? Spacing on the poles,
etc. Any help would be appreciated.
Thanks,
Terry, WK0F

3158. Dimensions for 4 band Hex - 20/15/10/6 ?

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-05-10 12:42:12 UTC
From: dekockwillem
Topic: 3158 Message: 3158

Hi all, I would like to construct a 4 band Hexbeam to cover 20/15/10/6m and don't need the 12m and 17m bands as I don't have a Rig that covers those frequencies. The 6m band is just an extra if possible and will eliminate the need to put up another antenna for 6m as I am limited with space on the tower. If 6m proves to be a problem, the dimensions for a 20/15/10m Hexbeam will be ok.

Hope you can assist!
73's de Willem

From: dl7io
Topic: 3142 Message: 3159

Hey Darren, the new law is not confirmed yet and still in the
negotiating phase but probably will be coming until summer.

So I first have to try to find a budget for a 6m rig before I start
with antenna work...
As in every economy our family also has more applications running
than the budget has possibilities. And I got 3 girls against my
vote...

I would not bet that I will be one of the first new signals on 6m.

Nevertheless I can measure here already...
73 Holger

PS Dick: Is Aisea 3D2AA still living in Sigatoka or did he move to
the Pacific Harbour area already?
I visited him a few time and even have been in the sugar factory
where he worked´this time.

3161. Mast/Tower & Rotor?

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-05-18 03:17:18 UTC
From: kc0rdg
Topic: 3161 Message: 3161

Hi all,

I'm fairly new to the group. I am going to be buying or homebrewing a Hexbeam sometime before winter sets in, from what I gather, this antenna is the best set of compromises I am comfortable with.

I am looking for some good recommendations on a mast/tower for the HB and a rotor solution. I'm aware the antenna is pretty light and thus the requirements aren't as much as say, a SteppIR, but I am unsure of exactly how light one can go.

I'm looking for brands and models of both that are known to work really well for this application. I was personally leaning towards something like a Yaesu G-800DXA and some kind of crank up mast or tower. There is a 40' crank mast made by US Tower that supports 6.8 ft of wind area at 70MPH. My reasoning for going with a crank is because I could lower it if bad weather is approaching or if I go on vacation, etc. I would buy new, not used.

Thanks for the replies,
Elijah

Elijah,

I've been using the commercially made 5 band Hexbeam for 5 years. My installation is a bit unusual as I have the rotator mounted a few feet off the ground and it turns a 30 foot push-up mast on which the Traffie Hexbeam is mounted. Together the mast and antenna weigh about 40 lbs. I use the Yaesu G-1000DXA. It is a bit of overkill given the mast/antenna weight and windload. However, I figured with snow and ice loading I wanted to be a bit on the safe side.

Anyway, if you are considering a more conventional installation...tower, short mast, and rotator in/on the tower then the G-800DXA should be fine.

Would the Yaesu G-450A work? I live in Minnesota, we do have ice and snow here...

Well I dont know about a hex beam but, I have a 450a on a vhf/uhf stack with a 4 ele 6 13 ele 2m and 10 ele 432 with a commet gp15 ontop for two years here in New England and the most it has done is rotate on teh mast. This is mostly because I have the rotor mounted on a cheap TV mast at about 20ft. bracketed to the side of my house. HTH

Not sure. If the G-450A is mounted in a tower with a short mast I would think yes. However, I tend to be conservative on these thiings and prefer to "over engineer". The last thiing I want to do is climb a tower or roof to fix a rotator because it was under sized. Rather spend the extra bucks and have margin and peace of mind.

By the way I tried the 450A on my configuration and it was too light duty.

Harry

For what it is worth

I use a Rohn 50 foot telescoping mast. I did away with the uppermost section(weakest)
And I have it bracketed to my qth. The Hex is at 38 feet. It is guyed, and also spun with a medium duty TV rotor. Works great ! It also uses a neat little digital control box. And has a v remote control. The only draw back was...I should have locked the mast sections with the provided hardware...or used sheet matal screws. In some high winds it did move the sections a little. Nothing serious. But it is off about 20 degrees. Easy fix though.

I'm using the mast from hexbeam with a radio shack tv rotator at the bottom. Works well for me. There are some pictures in the Yahoo HexBeam Photos section.

Good luck and 73's

Harry,

What kind of push-up mast are you using? Is it guyed and if so, what sort of bearing do you use at the guy points to allow it to turn.

Subject: Re: [hex-beam] Mast/Tower & Rotor?

Elijah,

I've been using the commercially made 5 band Hexbeam for 5 years. My installation is a bit unusual as I have the rotator mounted a few feet off the ground and it turns a 30 foot push-up mast on which the Traffie Hexbeam is mounted. Together the mast and antenna weigh about 40 lbs. I use the Yaesu G-1000DXA. It is a bit of overkill given the mast/antenna weight and windload. However, I figured with snow and ice loading I wanted to be a bit on the safe side.

Anyway, if you are considering a more conventional installation...tower, short mast, and rotator in/on the tower then the G-800DXA should be fine.

3174. Hex Beam wind load calculation/estimate?

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-05-18 20:31:58 UTC
From: ve3mic
Topic: 3174 Message: 3174

Since we seem to be on the topic.... Has anyone calculated(or best estimate) the wind load data for a 5 and hex beam?

3175. RE: [hex-beam] Mast/Tower & Rotor?

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-05-21 12:14:36 UTC
From: we1x@comcast.net
Topic: 3161 Message: 3175

David,

I bought the HDX mast from Traffie Technology when I purchased the 5 band hexbeam. Base of mast is about 2" with top section about 1" or 1.5". 4 sections I believe. Mast is of very good quality..recall Mike Traffie telling me the mast is from a flag pole company that adapted a pole design to be a mast. Mike had an option where you could purchase the regular mast or one that came in anodized bronze (blends in with the trees) which I did.

The mast comes with two guy rings for 3 guys at each ring. The mast rotates nicely in the rings. No problem. The mast also comes with two adaptors. One is a short "mast" the other is about 3 or 4 feet long and provides a bit more height. I use the short one as (a) the antenna, mast, and long adaptor become a bit unwieldy when putting the whole thing up, and (b) with the extra height I would have to remove or prune more trees..which wasn't going to happen.

Dug about a 5 foot hole and filled it with about 200 lbs of Quikcrete. Mounted a length of galvanized steel pipe in the hole with about3 feet of pipe above ground. On top of the pipe I mounted the Yaesu G-1000DXA.

Assembled antenna on mast, guys on the mast.

It takes at least two people (should have 3) to move mast/antenna assembly and lift onto the rotator. The mast/antenna assembly is not heavy, but unwieldly..so you need two people to help you maneuver and set into the rotator.

Make the necessary adjustments to ensure antenna is pointed north, etc.

For guys I use 5/16" double braid black antenna rope...Overkill regarding size, probably could get away with 3/16". Be sure to STRETCH the rope before using as guys as the rope does stretch over time and you will be repeatedly taking up slack. At the mast end I attach the rope to the guy rings using "quick release" clips..believe the hexbeam manual describes them.

On the ground the guys are attached to "dog run screws". These you can get at a pet store, Home Depot, etc. They are big corkscrews used for attaching dog runs or leads for those of us who put pets in the back yard and don't want Fido to go off chasing Spot in the neighbors flower beds.

To avoid having to tie and re-tie knots when readjusting the guys I went to Home Depot and purchased 6 "rope pulls". These are spring loaded little contraptions that you feed the rope through and when you release the unit it clamps down on the guy. If you need to tighten you simply pull more rope through the "pull". If you need to loosen you press the "pull's" plunger. Makes things a lot easier. Attach 2 "rope pulls" onto each "dog run screw".

When adjusting the guys make sure they are tight, but not overly so. The guys are to steady the mast/antenna and minimize any swaying (otherwise you will crack the rotator and all

comes down). If you make the guys too tight you are putting a lot of downward pressure on the mast and rotator ... which add unnecessary stress. Every month or so I check to make sure the guys are not too loose.

That's it. Been up for 5 years. No permit, no excavation. No problem with neighbors. XYL-accepted (but not necessairly approved). If I need to take down probably can do the whole thing (with some help) in 30 minutes or less.

Hope this helps.

Harry

From: Colin
Topic: 3161 Message: 3176

Hi Dick
I use an old Emotator (1102MXX..it`s so old i can`t find the specs
but i suspect it`s similar to a G400).
It used to turn a 3 ele 10m quad and handles the hex with no problems
at all.
A little off topic, but i wondered if you ever got around to doing
that side by side comparison to the cobwebb antenna?

3177. 40 meter Hex Beam spreader length

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-05-22 17:51:36 UTC
From: Ron Weaver
Topic: 3177 Message: 3177

I have decided to build a 40 meter Hex Beam, may inlude 30 meters as well if the 40 portion performs well.

In shopping for spreaders I am unclear of the length required to accomodate the two 40 meter elements.

Any formula's or practical applications out there in Hex land?

All the Best

Ron - W6OM

Hello Ron,
spreaders have to be 6m long.
Data an EZNEC-model can be found on my webpage
www.hexbeam.de under data & files.

Element wire: bare copper wire of 1.5mm²
distance between 40/30m wires 100 cm.
If you use insulated wire, elements will be shorter 3-8%, depending
on kind and thickness of wire insulation.

40m:
length of half reflector: 1134 cm
length of half radiator: 1072 cm
lenght of reflector insulator: 9 cm
length of radiator insulator: 10 cm
30m:
length of half reflector: 787 cm
length of half radiator: 766 cm
lenght of reflector insulator: 15 cm
length of radiator insulator: 19 cm

73 Holger

PS. I have prepared elements and insulators in stock.

The 40M Hexbeam would be approximately 11.4M
across at it's widest point - spreader tip to the
opposite spreader tip. (5.7M turning circle).

spreaders have to be 6m long.
Data an EZNEC-model can be found on my webpage
www.hexbeam.de under data & files.

Element wire: bare copper wire of 1.5mm²
distance between 40/30m wires 100 cm.
If you use insulated wire, elements will be shorter 3-8%, depending
on kind and thickness of wire insulation.

40m:
length of half reflector: 1134 cm
length of half radiator: 1072 cm
lenght of reflector insulator: 9 cm
length of radiator insulator: 10 cm
30m:
length of half reflector: 787 cm
length of half radiator: 766 cm
lenght of reflector insulator: 15 cm
length of radiator insulator: 19 cm

73 Holger

PS. I have prepared elements and insulators in stock.

3182. HX-5Bi, 40m? Also, RF choke needed?

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-05-25 05:06:02 UTC
From: kc0rdg
Topic: 3182 Message: 3182

I am wondering if anyone out there who has the Traffie Hexbeam is able to get it on 30 or 40m with a tuner. If so, how is the performance, both RX and TX?

I was going to order 6 of these http://www.marvac.com/detail.aspx?ID=22298 and install them near the coax-antenna connection. Is a RF choke _needed_ with the HB?

Thanks

3183. One year update

Hello all

Well the hex has been up a year.

All I can say...it is as good, maybe better than advertised.
I find it very potent for a "small foot-print" beam !
I have worked much dx, both in the Pacific, and Europe...including
The mid east. I keep pinching myself, as time , after time, I keep
breaking pile ups with medium power.

It performs great on all five bands, and the swr is flat (1.1 to 1.3)
I am considering a 40 meter hex..but I just do not know how to sqeez
it in.

Mine is at 39 feet. On a Rohn push up mast. I turn it with a channel
master rotor. So far it has been through 60-65 mph gust's no issues
with the antenna. I did have the mast section move about 20 degress.
But that was my fault for not locking properly...easy fix !

It may be a little pricey, but for the size, and performance...I
would buy another.

Ferrite beads are used on my G5RV -where the ladderline connects to
the coax. About 8 of them are used and the RG-8/X fits nicely
through them.

I've also heard others just making a coax choke balun by winding up
18-21 feet of coax on an 4-6" non-metal pipe/tube(as a form.

I checked the site that you listed above, and they cost $6 a Piece! -
holy cow!

I've loaded my HX-5BI on 40 meters using the internal antenna tuner on my PROII and it works pretty well but doesn't seem to have any directionality. I find it quieter than my Carolina Windom and more sensitive so I use it on 40 instead of the Windom. I tried to load it up on 30 meters but the tuner can't bring it in. My guess is that a wider range external tuner could bring it in and similar results would be had. I've also loaded it up on 6 meters but again the directionality is iffy.

imagine you are beaming North on 6M, the Hex will have a null to the
North but two big lobes, one North West and one North East. I can
park my Hex to the East and put a reasonable signal into SM/OH & LA
and at the same time work Italy, great for contests!

Interesting. I listened on my Caolina Windom 80 versus the HX5Bi on 40M. A signal strength of S9 on the HX5Bi would be 20dB over on the Windom.

sometimes I just gotta say something...In a nice
way..Ya know Duke, Its no surprise that an antenna
made for 20 and higher performs poorly when compared
with a gain antenna for 40....Of course if you
consitently are 6-8khz wide running SSB this could be
a difficult observation to make. LOL! 5-bander traffie
makes ia a good compromise antenna for the bands is
intended. It can be forced to work on other bands with
a good tuner. GOOD means not the wimpy ones found in
the all in one box computer assisted radios or is that
radio assisted computers..I digress. Anyway if ya want
40 meters reach into some of that money you wasted to
be wide on ssb and get with ol'Traffie on a new 7 band
hex-beam...If he can't build it maybe holger or I can
get you all fired up....AND IF YOU ARE CRAZY ENOUGH
AND HAVE THE CASH...AKA LOTSALOOT...We can put togther
a 11 band design that will include 60 meters...But
remember you could only run abt 20 watts on 60 and be
legal....YOU MUST PROVIDE THE ENGINNERING FOR THE
ROTOR!!!>>>LOL!
On the more serious side a choke balun will work fine
on the hex as will a bead balun...Just wind 10 turns
on the vertical mast, tape it up and have fun..W4HV

My Carolina Windom is not at a very favorable height and probably isn't set up for maximum efficiency. My Hex Beam is higher up so that might be one of the reasons. I generally get about 2 S units better reception on the Hex Beam.

3193. Off Topic: Wilson WR500 rotor

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-06-07 22:24:04 UTC
From: Ray Keefe
Topic: 3193 Message: 3193

Does anyone know where I can find the rotor end connector for a Wilson WR500 rotor. The control box uses a standard 8 pin male octal plug, while the rotor end uses a screw on 8 pin female plug. Similar to the Ampenhol mike connectors.

I have already tried to 2 rotor repair shops and nothing. The company that made the rotor went out of business in 1979 so no new parts are avail for it.

Thanks,

Ray

3195. feedline

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-06-08 17:41:23 UTC
From: Darren G0TSM
Topic: 3195 Message: 3195

On Traffie's Hexbeam, does anyone know what the impedance of the feed line between the elements is?.

The reason I ask is that I've built another hexbeam but have been playing around with the feedline between the elements. So far RG58 produces the best swr curves. On my current Hexbeam I use 10mm/2 pvc cable with 1mm insulation, Eznec show's this to be about 90-Ohms, is this correct as I can't find a feedline calculator program, anyone?...

73 Darren G0TSM

Darren, Don't regard that as feedline...Regard is as a part of the antenna length and you will discover something! This antenna ia a parallel dipole with a reflector...SURPRISE!!..all those fancy calculations are not needed if you take thia into account...Also the rg-58 coax is so lossy that the reflected probably isn't getting back to your meter to be measured.....Mike W4HV

From: dave@zievid.com
Topic: 3195 Message: 3198

Hi Darren -

FWIW, I experimented with 3 different wire feedlines on my homebrew hexbeam (http://www.zievid.com/W6OT/Hex/Beam.htm) before trying coax and solving all my SWR problems. With wire, I just couldn't get a good dip on all 5 bands, especially those that were far away from the main coax feed point. I think there was too much interaction or radiation on those short feed sections. Other people have had success with wire, but I couldn't get it to work.

If you can get a short section of higher quality coax, I'd use that. Otherwise the RG58 will do OK, but you're always going to be limited in the power you can use. Some RG8, RG213 or other larger, low loss coax would give you the ability to apply more power some day in the future.

As for the power losses others have suggested, I personally don't think that's an issue. Given that your main feedline must see something near 50 ohms at the antenna to be resonant (and have a reasonable SWR), there isn't a really bad mismatch between that point and the wire elements of the band you're using. Even if there is a little mismatch, we're talking about a few feet here - not enough for a significant loss. You can calculate how much you'd loose with a calculator like the one at http://www.ocarc.ca/coax.htm

For your main feedline, however, I'd suggest something other than RG58 if you can swing it. Using that same calculator, you can get an idea of the losses you'd have between your radio in the shack and the antenna itself. The money spent here is usually a good investment.

For example, 3 feet of RG58 with 3:1 SWR at 28mhz has a loss of 0.101 db - 100 watts at the output end of the main coax translates to 97.7 watts at the end of the short 3' feed stub. That's not anything you'd notice.

In that same situation, however, let's say your rig is putting out 100 watts into a RG58 coax run going 100 feet to the antenna. It would burn up about 48 watts in loss, so half your power is spent heating the coax. In the same situation, RG-213 has about half the loss. Keeping the SWR at the antenna end down, and using the shortest reasonable coax run, will help you put the most power into the ether.

BTW, if you do go with coax, be sure to weather-proof it well. Any moisture leaking into it will cause it to deteriorate and then you definitely can have more problems.

Hope I'm making sense,

73,
- Dave

Hello Darren,
90 Ohms are much to high! I call this a low impedance line.
You can reduce Z by reducing the distance between the 2 wires, or
increasing the wire diameter. The distance can be significant reduced
by cuting of the pvc-insulation of one of the wires. Than you have
other values for the dielectric material and a lower distance.
I have measured the Z of the "low impedance line" for feeding the
elements and it should be around 50 Ohms. This may be the reason why
you have better SWR curves with coax... 5-10 Ohms difference are not
critical because of the very small pieces of wire between the elements.

Nevertheless the feeding system is part of the radiators regarding the
electrical length! Therefore I would not suggest to use coax. A good
SWR has nothing to do with antenna gain! One would have to simulate the
antenna again with a coax feeding. It is easy to lose 1-2 dB and if you
have only 4 dB gain over a dipole...than we are talking about 50%.
On the other hand I guess the handling of the coax pieces is more
difficult than using a copper wire.

5-6 years ago I also made some tests with coax feeding but I came back
to the wire. There were no advantages using coax and a wire feedline is
much easier to build.

Jerry,

The Amphenol 4 pin mike connectors that were used on some cb radios and Motorola control heads was the best way I could describe it, these are 3/4" in diamter and came in 4 or 5 pins with a keyed screw on shell. The radio usually had the female and the mike had the male.

The one on the rotor is 1" in diamter, keyed like the mike plugs, male pins, 7 in a circle and 1 in the middle. So the mate is a female socket inside the screw on shell.

There are no identifying manufacturers part numbers on it, that would make this far too easy.

I figured someone out there may have had one of the rotors and perhaps has the end kicking around but not the rotor.

3203. End Spacing Paradox

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-06-15 11:39:27 UTC
From: rkbower
Topic: 3203 Message: 3203

I'm in the middle of a project to build a 3-band Hex Beam (20M-17M-15M).

Here's where I stand in the project:

I have the antenna mounted on a short pole in my back yard so the 20M elements are no more than 6 feet above ground. I am using an MFJ SWR Analyzer on loan from a co-worker to check for resonance and SWR.

I have trimmed each director and reflector to give me resonance where I want it to be -- close to the middle of each band. However, the analyzer initially showed high SWR readings -- Minimum of 2:1 on 20M, for example.

Through experimentation, I have found that decreasing the director and reflector end spacing (moving them closer together) lowers the SWR. In fact, the closer together I move the ends, the lower the SWR reads.

At this point, I have resonance on each band where I want it with SWR readings ranging from 1.2:1 to 1.7:1 within each band.

However, here's the paradox... To get these readings, I have moved the end spacing much closer than the formulas would project. On 15M, for example, the ends are within 3 inches of each other. The 20M element ends are probably within 6 inches of each other. I can provide more precise measurements, if necessary.

So... should I leave the antenna as-is when I put it on a mast or is it possible that some type of ground effect an causing this anomoly ?

Any advice or similar observations would be greatly appreciated.

From: douglis88
Topic: 3204 Message: 3204

I am planning to build a 3 band hex beam 10/15/20. I already have the fishing poles:) There seems to be a lot of discussion about feed lines for connecting the multiband elements downward or upward along the center post. I wonder if I should simply terminate all my elements at the same point (15m), so my hex beam would be like a multi-band dipole where all elements are fed at the same point. Any comments?
..Doug VE3EFC

Hello Friends,
I also am planing and gathering the material for a 5 Band Hex, and find that this is a very interesting point. It may well be worth a try, although much professional effort has gone into the accepted model (especially the end spacing on the elements, etc.). Has anyone tried this before?

3206. 5 band Hex Beam Project

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-06-18 17:19:19 UTC
From: w0tmm
Topic: 3206 Message: 3206

I have finally got all the pieces together for my Hexbeam Project.

I have run into two problems so far.

My spreaders are fiberglass from Max-Gain. 4' of 3/4" O.D. with 8' of 1/2" O.D. slid 6 inches into the 3/4" piece for a total length of 11' 6". I had a hard time getting the 20 meter wire level. No matter what I tried with the 41" long center post I could not get the wire level at 113" from the center post. I made another center post 47" long and the 20 meter wire is level now.

Once I added the 17 meter and 15 meter wires my spreaders were pulled out of shape, they were no longer perfectly striaght up. So I now have to go back and try to straighten the spreaders up by adding support lines. I had the support lines run from spreader tip to spreader tip.

I guess I need to add more support lines between the spreaders at the 17 and 15 meter level.

Any suggestions from those who have had similar problems with the hex bean?

John

Hi John
The wide variety of materials used for spreaders will alter the post length somewhat.
Too flexible and they tend to lift upwards at the perimeter instead of bending from the base.
As you add wires they may bend in "S" shapes and require additional support lines.
You will have a fine balancing act to manage..if one of the inner support lines is too tight it will allow the outer ones to sag.

Stick with it and you`ll get there in the end, the 60 mile hike around the antenna isn`t too much fun though :)

I`m surprised no-one has built a hexbeam with straight rigid spreaders at 30 degrees, it would need a 2m post (6`6").

The turning circle of the beam would stay the same and the element positions are standardised due to the no-bend spreaders.
6 further diagonal struts would be added between centerpost and spreaders for rigidity.

As a bonus, the entire hexbeam could then be folded up by pulling the speader baseplate down the mast (much like a rotary clothes airer)
It would be much easier to handle a folded hexbeam at the mast top than the unweildly fully deployed one.

Colin:

Interesting idea!

I am guessing that any spreaders rigid enough to remain straight with the tension of the wires being pulled even moderately taut, would also add a good bit of weight, especially if the other "diagonal struts" are added.

Of course, a monobander hexbeam could definitely be built with rigid spreaders and no "diagonal struts" at all.

Hi Leo,
It`s probably not better than the usual way to build i agree but it may be worth thinking about.
It would add weight(a few kgs perhaps) but the antenna should still be very light compared to other beams.
With the extra post length below the 10m element you could easily add extra bands (6m/4m perhaps).It adds to overall height and further isolates the elements from the metallic mast/ spreader baseplate.

The spreaders are the most expensive part of the antenna really and the bend is important to the element spacing on the post.

If any type of rigid spreader could be used it would be much cheaper and probably easier to build.
The braces could be perfectly horizontal instead of diagonal allowing for even greater drop when folding the antenna. Everything would use pivots instead of rigid fixings.
The elements (and gravity) would be the support for the spreaders,the braces simply prevent them from lifting (and dropping in the event of a wire failure).

They could also reduce the risk of the antenna inverting in the event of a support line breaking..especially that long top one.

Having the option to fold the antenna might be very useful to some for stealth, portability or perhaps getting the hex on a wall mounted mast in a small garden. The coax would stay connected as just the base of the spreaders move.

The spacing of the bands on the post is somewhat different, but according to the model it doesn`t seem to affect the performance much.
The element lengths/tip spacing may need adjustment, but it would take a more competent modeller than me to confirm that :)

John,

With the few Hexbeams I've made, I've always found getting the correct tension in the spreaders and wires, and getting the wires to be horizontal is the most difficult task. Like yourself I used Maxgain spreaders in my last Hex, and found these to be too rigid, and don't give quite enough flex !! They are great quality though !!

On my first Hex, I initially held all the spreaders in place by tying the tips to the centre post with poly rope (a little bit shorter than the required length - approx 9' from memory). I then wired up all the elements and made adjustments so they were reasonably tight and level, and then removed the ropes. This has the effect of allowing the spreaders to spring out a little, and takes up the slack in the elements. This worked well with my doweling elements, but not sure if it will work with the more rigid maxgain elements.

Good luck

David, VK2NU

anopther source for spreaders is mcmaster.com
they have fiberglass rods in almost any size.
you might try the 3/8 size it flexes enough to work around
slight corners I thought of it on a chimney brush.

Hi John,

I think 3/8 (10mm?) diameter would be too flexible for a 5 band hex.
Ideally the spreaders should be under constant tension so they can`t
move upwards or downwards.
My observation is that, apart from the likelyhood of the spreaders
bending into the usual "S" shapes, the hex will attempt rebalance
itself in windy conditions by shifting the wires.
If the wind hits the hex on one side, very flexible spreaders will be
pushed upwards. The speaders on the leeward side will tend to be pushed
downwards by gravity and the extra wire lengths given up from the
windward side of the hex.
If the spreaders don`t have enough "spring" to return to the starting
positions (with enough extra "ummph" to overcome the wires resistance)
the elements will remain where the wind blew them.

You lock the wires so they can`t slide, but gusty wind could eventually
break the element due to the tugging as the spreader bounces up and
down.
Adding support lines from the centerpost to spreader tips won`t prevent
this type of movement with a very flexible spreader.

Hello all,

I've got a 6M hex tuned to 52.0. I used CPVC for the spreaders and found that to be a pretty good and economical choice. Regular PVC is a bit stiff and Gold line is way too whippy. When building a hex -- measure measure measure. Take time when you wire it, too. And make yourself an RF choke with a few turns of coax. I think they work pretty well -- mine does anyway. Don't know about a multibander; personally I'd probably do no more than a couple of bands (just my preference). 73 and good antenna building -- Ray KE5ICG

Reference my message #3203 posted on 16 June...

I'm getting ready to put the antenna in the air within the next few days.

This Group seems to hold most of the knowledge base regarding Hex Beam antennas. Does anyone have any last minute advice as to what I should do regarding the end spacing ?

Thanks for any and all responses.

Here in Ardmore, OK 2 members of the local Ham Club have recently built
20 meter monoband Hexbeams. I helped build the first one and we just
spaced the ends of the elements evenly(9 3/4" spacing was just divided
about 4 7/8" either side of the center spreader). The antenna worked
well for the user. Later I built one of my own and utilized the complex
formulas (triangle sides) to locate the element ends. If there's any
difference at all between the two antennas it may be the simpler method
worked best. It may also be a case of the total
shack gestalt being better with the first one. Both appear to work OK.
You might want to consult W1GQL's Hexbeam website at this URL.....
http://midcoast.com/~w1gql/hex/buildyour.htm
We used the element info from that site to build both our Hexbeams.

Ron,
With all the guru's here you probably realize that
this is a high class bent fan dipole and
reflector...End spacing is like trimming a dipole
.....DONT TRIM THE REFLECTOR!!!...(Trade
secret..don't tell!!!)if you measure from the point
that you transition from coax on the feed system it
is very very close to dipole measurements on the
driven side...But don't tell!!!..LOL!!!Good Luck..no
two designs are exactly alike and all need minor
adjustments unless you are the luckiest guy
around..!!!

Hello Ron,
congrats to your nice project.

Let me explain something for the understanding of the antenna.
There is a big difference between antenna gain and a good SWR!
The reflector length is determining the antenna gain. The DE (driven element)length is mainly important for the SWR. The end isolators are more influencing the SWR but also the gain.

The best gain is far away from the best SWR and also not equal with the best F/B.

The best results for a max. gain optimation you would get with a 25 Ohm design. This would be no problem for a monoband version if you feed via a quarter wave coax stub (37 Ohm or 2 x 75 Ohm coax in parallel). With multiband versions this is a bit harder and so we made designs for direct 50 Ohm feeding.

Depending on the location of the feeding point (top or bottom) the DE lengths vary. This can be seen if you compare the relation of the element lengths for reflector and DE in multiband design.

With cutting and trimming the elements you will only know that your antenna has a good SWR. But you have no idea how about the gain after all. As the gain is the feature that is the most difficult one to measure you have to model your antenna to find out how it will work.

So nobody can tell you anything regarding your final design but I guess that you will be far away from max. gain.

The best gain is in the cw portion of the band where in my designs the SWR is close to 1:2. Here you have about 4 dB over a dipole which makes an remarkable step. Over 300-400 kHz bandwith you lose about 2 dB gain. The SWR is much better here but the gain is diveded by 2 compared to a dipole.

So my suggestion is: Make an optimization based on a computer model. Build this model. The difference between model and reality should be very small or with your model is something wrong. If you are close to your model and want to tune the antenna a bit, than keep all the relations between the wire and isolator dimensions as they are.

73 Holger

PS. I will be DQ2006D for a week starting from Saturday

Holger --

Thank you for the quick reply. I only wish that I had the mastery of antenna theory that you and many others have.

Perhaps your answer is imbedded and I'm just too think to see it, so please excuse me if I'm being too dense. So, here goes...

In your opinion, do you think I am better off to stick to the end spacing as determined through computation or should I stick to the end spacing that gives the lower SWR readings ?

Thank you,

Ron, AC2C

3219. Five band 20-10 Quick-Hex Beam for under 500 bucks survey

Yahoo group: hex-beam (2001 — 2006)

Topic: 3219 Message: 3219

I am a big fan of the Hex Beam. I have built a 5 band hex beam and I really like it. I am currently in the developing stages of a hex beam that is 80 percent preassembled. So far it looks that I would be able to sell it for under 500 dollars. All the wiring will be allready attached to the center pole and the fiberglass poles, that in turn hinge on the center hub. For ease of shipping the antenna will ship with the fiberglass poles collapsed and hinged up. All you have to do is strectch the telescoping poles, hinge them down and lock them in, and then lock in the wires along the poles in peselected locations. I imagine that total assembly time would be about 1 hour, maybe less. All the connections come allready sodered for long life. This will also work very well for a portable hex beam for the Field Day.
This is what I imagined so far... :)
This is just a survey to see level of interest that there is out there for something like this. Please let me know what you guys think.
Any comments are welcomed.
Thank you...

Ion and All,

I have been a Hex-Beam user for six years and have been highly impressed with the quality of the Traffie-built antenna. In addition, I have helped install two others and both performed fine. I also have the 6 m Hex-Beam and the 40-30 m Hex-Beam.

Ion, if you are able to make a quality 5-band Hex-Beam and sell it for USD500, then I sincerely wish you great success.

However, I can't believe anyone can sell this antenna for USD500 and be of reasonable quality. Why? I have a good appreciation of the cost to build the Traffie Hex-Beam. He charges USD989 presently (it was USD600 when I bought mine years ago) and makes only a modest profit. Furthermore, Holger has also taken the plunge into making and offering parts from which to construct his version of the Hex-Beam. From those I know that have acquired parts from him, they all comment on the fine quality. Just to buy the parts from Holger will cost you about USD837. You have to also include shipping for both, but for those living in the USA, the added S&H from Germany closes the gap between the price of the two.

In any case, both are well more than USD500. With Holger's parts, you have to do your own tweaking. He does offer a complete antenna on special order as I recall for an addition fee ... likely a total close to the Traffie antenna. Each Traffie antenna is fully assembled by Traffie, tuned, tested, and then disassembled for shipping. It takes only about 1-1/2 hours (the first time) to assemble and get the antenna up in the air.

I hope this note provides a bit of material for Ion and others to consider the cost reality of making a quality Hex-Beam type antenna that will perform and last for many, many years. For my part Ion, I simply don't believe you can achieve your price goal of USD500 for a 5-band version that meets the quality, performance, and life-time people expect.

Nevertheless, give it a go and maybe you have or will find a way to manufacture the antenna more cost effectively than anyone else.

Good luck es 73,
Barry W4WB

My opinion on this is quite simple: You might consider asking permission from the guy who had the idea and created the concept, as well as starting a business based on HIS OWN ideas, rather than just capitalizing on his work by cheapening the design. De N1FQQ

I am glad you feel that way Web. I am sure traffie will love you for it...I can build a superior design that is easy do deploy for much less than 500 so I am sure ION can make a buck at the 500 mark...after all hams are a cheap and cantankerous lot..Of which I are 1...LOL...W4HV....By the way its still just a fancy bent fan dipole...with a reflector!

I am most impressed by your claim Mike. Can you share your superior design with all of us that can be manufactured for < $500? Perhaps your labor is free? Quite a claim, so kindly explain!
73,
Barry W4WB

It sounds very impressive and the price would definitely be a plus. I have a HX5BI which I like very much, but I know that most people may be put off by the price. The Hex Beam is definitely a winner and it could easily be a super sell if you can offer it at a reasonable price and also do some good marketing. It also sounds as if Mike is thinking of retiring from the antenna businss and if no one else steps up to the plate and buys his business then the ham community would no longer have access to a commercial version of the Hex Beam. I think that the Hex Beam is one of the most innovative antennas around and could become a big volume item when done right. A six meter option would also be great. Don't know how hard that would be without screwing up the other bands. Also in the future a 40/30 meter duo-band version would be nice. Good luck with your venture.

I'd do it in a heartbeat. Two main things you MUST make sure are good: Quality and Performance. Does it hold up to strong winds? Will it stay together for years? Does it perform well? I'd gladly fork over the money!

I would buy a Hex but they are out of my price range. I can understand that an antenna is MOST of your station and many hams have no problems spending 1k+ on a radio and yet whine about the price of the Hex. I think the reason is, when you pay for a nice radio, to get something that to make yourself would be really tough to do unless you have surface mount technology and really know what your doing. Now the Hex, it's really just some fiberglass and wires and to pay so much for something people could reasonably construct themselves (indeed many do and have), is a bit harder to sell. I honestly believe if Mike lowered the price to something like $500-600, they would be flying off the shelves. Selling more for cheaper is more work, but there are more out there and that in itself is advertising. Secondly, selling many somewhat cheaper might be more of a viable business plan than selling fewer that are more expensive.

Go to town and keep us updated!

If you have higher costs, you can't sell it for 500 bucks.
Than you would give money out with every antenna.

Out of an commercial view you would need to get twice the money to
run a serious business model. The margin making an aluminum beam is a
few times higher.

If I hear something of teleskoping fiberglas you can see rolling my
eyes... If Ion is going to produce a high quality beam he will find
out himself that this is different from fishing rods and will cost
you money. You can't go for a lightweight antenna with pultruded
fiberglas and you will not get the typical shape and needed pressure
with same diameter fiberglas. The crux of this fine antenna is that
you need other kind of materials. And those ones are very expensive.

Simply to explain you some relations.... Fiberglas is a product made
out of oil and the prices are depending on the oil prices.
I'm buying a few 100's of spreaders this year and paying about 50
percent more than 2 years ago where I have built only 5 beams!!!

The other main components are copper, brass and stainless steel.
Please finde out how those prices have developed over the past 2
years...

Welcome back to earth!

I have one of Holgers beams and the build quality is excellent.
I bought from holger instead of traffie because buying outside of the european union would have cost me import duties of 17%
It was not cheap but still cheaper than buying from the usa.
Quality costs, if you sell the antenna for 500 dollars then it will not be the same quality.

I could have homebrewed but to be honest work commitments made this impossible so I paid for the antenna, if I was building then I would have made it cheaper but then again how long would it have lasted ?.
I would homebrew cheap as I could repair but when my radio time is to precious to spend making the antenna it would also be to precious to repair it so I got a quality antenna that I know will last with minimum maintenance.

It is all a matter of what you want and the time you have to spare on the hobby.

how long would it have lasted?

Well, my homebrew 5 bander is well over a year old now and still
going strong :)
If it survives for just 3 years.. it`ll have cost me about £1 week!
The commercial hex in comparison (£700 over here) would have to last
13.5 years to equal that ;)

The spreaders are the most expensive part of the antenna and don`t
radiate rf worth a jott, but as Holger pointed out, the type of
fibreglass is vital to the bending properties.

Design a Hexbeam that doesn`t rely on the bend to gain rigidity and
you`ll have a product that might weigh slightly more.. but probably
cost even less than the $500 you envisage.

Imho,everyone should homebrew a 5 band hexbeam at least once :)

Hello Colin,
how many hours did you work on your beam and how did you calculate
your labour? While running this as a business you have to get paid
for your labour! And everybody who tried to build a hex knows that
this is time consuming.
If you buy one you will be QRV after 1-2 hours of work, depending on
your skills. But building/testing/preparing one takes all together
about 2 working days for a professional. This is not only the work
itself. But you need to purchase parts, search & check possible
deliverers, do a lot of paperwork and also the designing/testing
takes a lot of time.

You have to have this in mind if you talk about a business case.

If we would discuss this with a banker asking for money he would tell
you that the price has to be doubled to make it a serious business
model.

Hello Colin,
how long have you been working on your hexbeam and how much did you calculate per hour? If you run this as a business you need to be paid for your labour. Especially with an antenna like this which is very time consuming. I have calculated the working time and adding all needed working steps (including paper work like searching sources, purchasing, billing etc.) you need about 2 days per antenna as a professional!!!

I'm running this as a hobby business and selling a 5-bander (20-10m) for 700 Euro plus shipping. I meanwhile have sent a few to the UK and this costs about 540 British pounds incl. shipping.

And to give you an open book: In this price I have calculated with 2 □uro/hour... again in words "two per hour".

I'm not making any profit with this and my wife tells me everyday to stop this bullsh... and better spend the time with the family.

In principle she is right and I'm making this only because I like it (It's my hobby...) and I get requests from others who have no time or skills.

Fortunally I have another well running business which allows me to do so.

73 Holger

PS: 40m versions start with 1100,- Euro plus 50 Euro for every additional band.

Hi Holger
I agree that the labour is the stinger..hidden costs tend to mount up too, so you really should allow for 100% profit for commercial production to cover all the bases.

I built my hex as it didn`t seem any more difficult than other antennas i`ve homebrewed in the past, including a 3 ele hf quad.

I do like challenging projects, in truth the hexbeam was a "busman`s holiday" of sorts for me :)

I build a lot of geodesic structures so i`m no stranger to hexagons, my latest design consists of 450 individual struts that all have to be custom fabricated.
Now if i were to charge the true amount for my time and labour involved in these..i`d sell very few.

I guess it really depends how much enjoyment you get from building them against how much profit is in it.

I`ll stick to geodesics and leave the hexbeams to you, hi.

I want to thank everyone for their input. I am currently in vacation, but as soon as I get back I will start a little web site with some details and a lot of pictures of what I have in mind. Just to give you some more info on this beam, here are some points that might help:
*main hub is made out of welded aluminum and SS hardware.
*the poles are fiberglass and too keep the cost down I have a source of 16ft loong crapie poles that when used for this project (first 11ft sections) are very strong. The beam that I have up now use the same poles and for the last year went through some nasty winds. Still up and running.
*I am still trying to find a good idea of attaching the wires to the poles, but one day it will come to me :) . The antenna that I have up uses zip ties. They seem to be holding up well... but maybe another method would look more... proffesional :)

Well.. that;s it for now. I'll see y'all when I get back from Aruba.

Hi Ion,
Here`s my thoughts for what it`s worth.

For a single band hex your plan might work, but for a 5-bander it
won`t.
Using the thickest sections of a 5m fibreglass rod won`t give the
correct curve needed.
The immense strain on the rod needed to get even close to the correct
curve will almost certainly snap it off...either near the center hub
or at the transition to the 2nd telescopic section.
Cable ties can slip in wet/windy weather and hose clamps will easily
crush thin fibreglass.
Drilling thin wall fibreglass is not an option.

Good luck

What you'll find very quickly is that it's the labor in getting materials fabricated that is very pricey.

I used to work in the electronics industry; the two most common materials are copper and fiberglass-reinforced epoxy. Why? There is no cheaper dielectric than fiberglass-reinforced epoxy, and it's very difficult to beat copper for its conductivity per cost unit ratio.

Fiberglass is not made from oil, neither is epoxy, although both require energy for their formation into useful forms. We are paying at present approx $2 per pound for fiber-reinforced anything - sheets, rods, bars.

If someone wanted to make a hex-beam as a business, one would not purchase fiberglass, but instead, learn how and do the layouts on their own. Several of the screwdriver antenna companies do exactly that. Backyard mechanics have been doing epoxy-impregnated fiberglass for decades; it is only a touch more difficult than nominal woodworking. The silly way to run the business would be to find and purchase the fiberglass.

A key would be to find ways to semi-automate the fiber/epoxy lay-up process, so you don't spend many hours at it.

I'd be contacting guys who sail boats. Most of them do their own fiberglass lay-ups for masting. Many books are available to teach you how to achieve your goals of weight versus strength versus flexure capability.

The various dielectric blocks, presumably made of polyethermide, also need to be tooled up, so that it's not a long labor of torture for fabrication.

In the end, the raw materials should be far less than $100 for a 20 pound antenna that's made more of dielectric than conductor. It is the fabrication labor which will drive the cost.

From: Michael Baker
Topic: 3219 Message: 3240

WOW! After reading some of the replies I felt compelled to respond.

Let me preface my response to some of the recommendations given that I do not at present own a Hex Beam but I have been following the antennas progress for some time now and did throw one together for 10 meters a few years ago as a test antenna so I understand some of its weaknesses and strong points as well as some of the problems with building one from scratch.

The Poles.
My thought is don't try to reinvent the wheel. I have had to have items made up of fiberglass for a commercial interest I was involved in 20+ years ago and I can tell you from observation that it is labor intensive which equals bucks/cost so, unless you or your company has a LOT of experience manufacturing fiberglass poles, leave it to the pros. Much less headaches, cost, tooling, learning curve, etc. You might try Jackite. They make telescoping poles for supporting kites and pennants at sporting events and they make a 31' pole that starts out about 3/8" in Dia and tapers to about 2" so they might make you a deal on using a bit over half of the antenna at some reduced price. 31' pole is $50. They have others available.

Wire element attachment points.
Forget Zip Ties. They fail quickly in the Arizona Sun. You need something more substantial if you intend for it to survive the sun, Ice loading, wind and cold of various parts of the country.
You could use a section of rectangular stock fiberglass say 1" X 2" or 1" X 3" drilled out to fit the fiberglass tube attachment point with a captive screw and a screw point on the other end to attach the wire or a SS hose clamp with a bolt welded to the band for the wire to wrap around between two flat washers and then nutted when completed. Both would be cheep and not difficult to make or have made. I took hose clamps and drilled them out and ran a bolt thru them and used them on solid fiberglass rod for the elements on my 10 meter model and experimented with using 1/2" thick cut sections of fiberglass sheet drilled out and taped for some others to test them. Both work.

Materials are not going to be your biggest expense. Labor is. No one works for free not even you so remember if it involves time, it costs you money somewhere down the line.

In closing let me say good luck and let me know if you decide to actually get into the business because at the price you are thinking of, I would be interested. Also don't discount making the antenna a Kit of sorts and let the owner do as much of the building as possible. It's that Time is

Money thing again.

Sorry for the broken nature of that last posting of mine. I cut and pasted from something on another group. We were discussing dielectric materials and he gave us this text on G-10 type epoxy and fibreglass. Getting old.

3244. VE3EFC's Installation

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-07-16 11:16:46 UTC
From: ownsyar
Topic: 3244 Message: 3244

Hey Doug,
What a great installation! You have outdone yourself! Anybody who hasn't looked at Doug's webpage is missing out. I like your plywood base and the floor flange interface for the mast and I particularly like the plastic chain links. Heck I liked every thing about it. The single feedpoint looks good. I am curious about how a five band hex will work with this feed system.
Again great job, good luck and 73!
Allen KA5N

3245. Hexbeam SWR

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-07-16 22:44:41 UTC
From: John Cowan
Topic: 3245 Message: 3245

Now that I have managed to get my hex beam together I am wondering exactly how to adjust the SWR. I am feeding the antenna from the top. I took a prelimnary reading 3 feet off the ground and next weekend I will raise it 18 feet in the air to get a more accurate assesment.

14.150 reads 1.6 SWR, 14.350 reads 1.9 SWR
18.110 reads 2.6 SWR, 18.160 reads 2.3 SWR
21.200 reads 1.9 SWR 21.450 reads 2.3 SWR
24.930 reads 2.6 SWR , 24.990 reads 2.5 SWR
28.300 reads 2.3SWR , 29.700 reads 2.6 SWR

John W0TMM

Nice work Doug.

Good to see ingenuity in action.

I give you 10 out of 10 for originality, especially the mast!

It would be interesting to compare the predicted patterns of your hex
versus a standard design and what effect the various sloping elements
have.
The common reflector connection might allow for a simplified hexbeam
hat-loaded lowband vertical perhaps.

Thanks Colin,

My 3 reflector elements are independent of each other. There is no connection at the center post for the reflectors. They simply run inward to the center post then back out (3 insulated wires passing through a single plastic eyelet). It never occured to me to cross-connect the reflectors. I guess if they were bare wires I would have connected them all together. I wonder if it makes a difference.

Guys, I need some input here. I have read the posts about gain and swr. I do not have a computer model to work with. Just an MFJ-269 SWR analyzer. I would like to know if there is anything else I need to do to optimize the antenna before I put it on the tower. My wire measuements I got fromthe K4KIO web site. My feedline is #8 stero amp wire.

What I do not understand is the big difference in SWR from Band to Band. Is the difference just the end gap adjustment? or is it the interaction of the wires to one another?

Gain Vs swr ,,,,How abt simple thought...Best swr is a 52 ohm antenna....Unfortunate dipoles are 75 ohm at resonance....Not a great reality....Thats why the two never converge at the same point....So remember that you are working with a bent fan dipole with capacitive loading between the elements and a common feed point ...add in the reflector and yep thats a hexbeam...computer models are not always accurate because of the physical reality of construction and material variance...whew work till you get one right then duplicate it exactly...wait we are constantly varying all the materials because we are hams....GOD HELP US...LOL!

You may want to try removing the feedline and see what the SWR curves look like when feeding each band directly. The feedline and multiple bands will interact in the final configuration, but it's interesting to get readings when it's working as a mono-bander.

I had a tough time getting the SWR curves on all bands on my homebrew (http://www.zievid.com/W6OT/Hex/Beam.htm) to work, and tried various types of feedline until settling on short pieces of coax fed from the top. Many other people have gotten parallel wires to work, but I just couldn't make it happen on all 5 bands at the same time - usually the bands farthest from the feed point had too high SWR.

Also, I'm not sure of the exact problem you're trying to solve - is the SWR not low enough for you, or the dip not in the right place?

FWIW, when I had to move the SWR curve to lower frequency on any of the bands, I shortened the wires of the driven element only and kept the end spacing the same. To get a lower SWR value, I changed the feedline to coax and got nice deeper dips.

Hope this helps,

- Dave

Don't know much about adjusting elements on hex-beams, but here's my two cents about interpreting your swr measurments.

14.150 reads 1.6 SWR, 14.350 reads 1.9 SWR resonant frequency < 14.150
18.110 reads 2.6 SWR, 18.160 reads 2.3 SWR resonant frequency > 18.160
21.200 reads 1.9 SWR 21.450 reads 2.3 SWR resonant frequency < 21.200
24.930 reads 2.6 SWR , 24.990 reads 2.5 SWR resonant frequency > 24.990
28.300 reads 2.3SWR , 29.700 reads 2.6 SWR resonant frequency < 28.300

So, for example, the resonant frequency for 17m would actually be above the 18.110-18.160 frequency range. In this case, you can start to trim the element until you get satisfactory swr readings in that range.

For 15m, your swr measurments indicate that the element is too short for the 21.200-21.450 frequency range, and you would have to add element length to improve swr.

Let me say that the above applies to a half way dipole. I really have no experience as to what effect this would have on a hexbeam, but it's just some food for thouhgt.

Best of luck and 73's

Hi Tom,

SWR measurements are not enough because you do not
understandif the SWR is high due to a high impedance,
plus reactive parts or lower than 50 ohm.

You may try as suggested by one colleague to remove
some of the dipoles and see what is changing.

For me you have length problems, see notes;

> 14.150 reads 1.6 SWR, 14.350 reads 1.9 SWR TOO LONG
> 18.110 reads 2.6 SWR, 18.160 reads 2.3 SWR TOO SHORT
> 21.200 reads 1.9 SWR 21.450 reads 2.3 SWR TOO LONG
> 24.930 reads 2.6 SWR , 24.990 reads 2.5SWR TOO SHORT
> 28.300 reads 2.3SWR , 29.700 reads 2.6 SWR TOO LONG
>
The SWR pattern is strange Long- Sort - Long - Short -
Long...

Michael:
I raised the Hexbeam up to 18' this evening. The swr measurements were as follows.

14.150 reads 1.4 SWR, 14.350 reads 1.5 SWR
18.110 reads 2.0 SWR, 18.160 reads 1.9 SWR 18.356 reads 1.4 SWR
21.200 reads 1.4 SWR, 21.450 reads 1.7 SWR
24.930 reads 2.2 SWR, 24.990 reads 2.0 SWR
28.300 reads 2.1 SWR, 29.700 reads 3.4 SWR

My question is to lower the resonant frequency on 17 meters from 18.356 to 18.130 do I adjust the end gap or shorten the driven element?

If it were a dipole, you'd lengthen it to lower the resonant frequency. I don't know about adjusting the end gap. I guess that's why I bought my hexpbeam from Mike Traffie :-) I think Traffie did a lot experimenting to get his design to work.

It is interesting that you're getting improved measurements as you raise the antenna. Maybe when you raise it to it's full height you'll be right in the ball park.

TRaffie di a lot of playing and then reproduces the result faithfully....On 17 meters make the driven a bit longer and it will fall in ...This will have a minor effect on 20 and 15...but not much...Yes physics do not change..Indeed you are messing with a bunch of dipoles...If you get to a 1.5 to one match you age probably at best gain (dipole resonant impedance is 75 ohms)...W4HV

Hey John,
nice project!

Before you start measuring SWR's you have to bring the antenna to a minimum height of 4m or 12 ft. If you are lower than 4m the capacitive coupling to earth and everything around will destroy all values. Going higher from 4 m does change the SWR mostly only marginal. The element coupling is in the magnetic field component and therefore we have not that influence of the earth if we have minimum distance like known from yagis or quads.
Of course no metal roof 2m beside etc. etc.

If you change elements start only with the half of the desired/expected length per band and measure again. Measure all bands again!. The surrounding bands are also influenced while changing the length. Before cutting a wire fold it back and measure. For longering the lements use e.g. luster terminals.

Try to keep the relations of the wires, means cut both or make them both longer! Don't touch the end isolators. Try to have a higher SWR in the CW portion to have more gain.
the 2 values given for 10m are not very useful as they are to far from each other. Go for 28.0/28.3/28.7 MHz. Usually that is the range you mostly will use. If the beam is broader up to 29.x this will be fine.

I'm not sure what you used for the spreaders and elements. But if your spreaders have another shape that changes the distances between the wires. This and other kinds of wire are mostly the reasons for the differences in the final result.

I wish you success
Holger

PS. Try to install the beam at 18m instead of 18ft ;-)

From: John Cowan
Topic: 3245 Message: 3258

I would like to thank all of you who replied on reflector and off. I have the SWR close on all bands but 10 meters now. I am gonna work on that one tomorrow. I plotted the SWR on an graphs I made from my Excel Spreadsheet and they looke very similar to the ones posted. I posted some photos on the Hexbeam Group Photos section.

dl7io <dl7io@...> wrote: Hey John,
nice project!

Before you start measuring SWR's you have to bring the antenna to a minimum height of 4m or 12 ft. If you are lower than 4m the capacitive coupling to earth and everything around will destroy all values. Going higher from 4 m does change the SWR mostly only marginal. The element coupling is in the magnetic field component and therefore we have not that influence of the earth if we have minimum distance like known from yagis or quads.
Of course no metal roof 2m beside etc. etc.

If you change elements start only with the half of the desired/expected length per band and measure again. Measure all bands again!. The surrounding bands are also influenced while changing the length. Before cutting a wire fold it back and measure. For longering the lements use e.g. luster terminals.

Try to keep the relations of the wires, means cut both or make them both longer! Don't touch the end isolators. Try to have a higher SWR in the CW portion to have more gain.
the 2 values given for 10m are not very useful as they are to far from each other. Go for 28.0/28.3/28.7 MHz. Usually that is the range you mostly will use. If the beam is broader up to 29.x this will be fine.

I'm not sure what you used for the spreaders and elements. But if your spreaders have another shape that changes the distances between the wires. This and other kinds of wire are mostly the reasons for the differences in the final result.

I wish you success
Holger

PS. Try to install the beam at 18m instead of 18ft ;-)

Mike,

I must agree that thinking is good, but getting facts correct is also a fine thing to do. Traffie has always suggested the best all around height for the Hex-Beam is with the antenna base at 40 feet, which locates the 20 m elements at 43.5 feet AGL. This is the 5/8 lambda height.

I have no idea why you are interjecting "snake oil" into the discussion. Can you clarify exactly your point please?

Tnx es 73,
Barry W4WB

Mike,
I'm not talking about the best height for "optimmum performance".
I'm talking about the minimum height needed before doing SWR
measurements. You need 4m or more to minimize the big influence of
capacitive coupling to the ground.
Sorry if that was not clearly written in my last posting.

Holger , No I understood completely...They work better
a bit higher but my point is still the same..Its basic
antenna theory.. We commonly call it ground losses,
capacitive coupling and or ground reflection. Oh yes
its quite obvious...Just Like a standard yagi, the
Driven element must be .2 to .25 Lambda separated from
any reflector to tune it...The ground also works as a
reflector allbeit a less than perfect one...

3265. Insulated Wire for Antenna Elements

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-07-21 19:42:07 UTC
From: douglis88
Topic: 3265 Message: 3265

Here is the story that explains why I prefer to use insulated wire for my antenna elements.

Forty years ago I was a teenager sitting at my desk doing homework for school. My coax connector had been unplugged from rig and was laying on that same desk. Suddenly, I heard and saw blue sparks dancing across the varnished surface of that wood desk. The sparks were coming from the loose coax connector. I ran outside and looked up at my quad. Guess what. There was a heavy snow falling, the kind of snow with big fluffy flakes. The bare wire on my quad was picking up a static charge from the falling snow. There was no lightning in the area.

I have heard the term "rain static" before. I wonder if it can be charged rain drops touching on the bare antenna wire, like scratching on your bare car antenna with a metal key. Does rain static occur only on bare antennas?

Since this experience, I have always used insulated wire for my antennas. Also, I provide a grounded connector in my shack as the resting place for disconnected feedline.

I wonder if anyone had similar experience. I wonder is anyone agrees with my theory about "rain static".

it not only happenes on wire antenna's but I had a tri band beam up in the air and the wx was perfect no rain and the sun was out ..it was a nice day .....well the coax connecter was not hooked to any radio and was open but i moved it and it fell against a metal cabinet and sparked and burned a big hole in it so there you go it does happen

Hi,

I am going to be getting a disassembled 5 band HEX Beam soon, model HX5-B, but without the installation/assembly manual. Does anyone have a copy one that could be sent to me via email? Or if not, is there a place on the interest I could go to download one?

You help is greatly appreciated.

3274. HB & Support Mast Help

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-07-24 23:41:12 UTC
From: Jim Chaggaris
Topic: 3274 Message: 3274

Greetings, I am currently thinking of buying a 5 band Hex beam to replace my so-so performing vertical. I want to mount it up about 45 feet on a push-up mast. Any thoughts on what's available out there at a reasonable price?

Also, are the aluminum stackable masts available on Ebay and elsewhere sufficient?

What about base mounts for permanent installations? I'd like to avoid sinking the mast into a concrete base for now. GAP offers a tilt base that looks interesting but seems light-duty to me and rather pricey.

Any help would be appreciated.

Hi Max,

I would also be very grateful for a copy of the manual.

email to mw0cdo at gmail dot com

As many of us are interested, why not post it at Yousendit?
Many people could then download and also saves you email time..

HYPERLINK "http://www.yousendit.com"http://www.yousendit.com

Or even post a copy in the group files area...

Cheers!

73 Paul MW0CDO.

Hi Jim
I use a Rohn 50 foot push up. I discarded the upper most 10 foot section, it seemed a little to Skinny...and light for the rotor and beam. I have it bracketed to the rear of my qth, and guyed. Works great so far. It has withstood 70 mph winds here on the east coast.
I think I paid about $130.00 shipped.
good luck

I think you made the right decision. I Have an old 40 foot pushup on my 20M monoband Hexbeam. We got an unusual springlike winter thunderstorm line thru here last January. Its high winds broke one of my spreaders loose from the hub and blew it over the top of the Hex. In addition I had my rotor mounted on 4 feet of the skinny top section of my pushup mast and the wind actually bent the top section slightly. I didn't remove the top section, but I did cut off the bent piece and only extended the remainder 2 feet to cut down on the winds leverage moment. Good luck with your mast.

Hi Folks,

This thread comes up at a very good time. I'm putting together a 20m monobander hex and was planning on using the Gap tilt base as part of the support system. But I have a need to make the whole thing self supporting. I can't use guys. I have a 25 foot mast elsewhere in the yard supporting an inverted V and the XYL is complaining about the guys. In addition, my lawn service is constantly running into them and chopping them up.

I was thinking about using the Gap base and supporting the mast part way up by bracing it against the house about 10 feet up. I have a new 33 foot push up I bought from Radio Shack some time back, but rejected using it because it seems to me that it just won't do without guys. I was planning on getting a 20 foot, thick wall aluminum pipe and using it as the main mast, with the hex mounted on top of a 5 foot mast and rotor, with no guys. A trade off in height, but better than nothing.

Does this sound viable?

Hi Pat,

I would suggest that you get another mast that is 40' or 50' long and allow the section to overlap several feet. You then drill a hole through the overlapped sections and secure with a SS bolt. This takes a rather limp pole and turns it into something quite stiff. Bracing at 10' will help at lot too. You should 25-30' easy this way, and it will withstand reasonable strong winds, but not 60+ mph with a good head load of 20-25 pounds. The thickwall AL pipe is not going to withstand strong winds. What is much better is to use thick-wall SS pipe. It can flex a lot and does yield as will the AL pipe. I had a 25' tall GAP Titan mounted on such a SS pipe about 8' AGL and about 3.5' in the ground. NO GUYS at all. It has withstood strong winds well over 60 mph. Yes, it does bend over some, but recovers just as one would hope. Now the problem ... thick-wall SS pipe is $$$.

Thanks for all those that responded. I'm still wondering if the thick-wall 1 7/8" diameter aluminum military mast (in 4' lengths) that sells on Ebay would be a viable option. I have about 50 feet of it with the guy rings etc..It seems pretty heavy duty and if I bolt each section together and guy the mast in at least 2 places, I feel it just might be suitable. Any thoughts?

3283. EZNEC Modeling

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-07-26 15:35:00 UTC
From: douglis88
Topic: 3283 Message: 3283

I am not an expert in antenna theory, but I purchased the EZNEC program last week and spent many hours modeling hex beams. The program is rather awkward to use, but its a lot easier than building real antennas (hi). I have modeled only simple mono-band hex beams so far. I have tried many combinations of end spacing and center spacing between elements. I tried many length differences between driven and reflector. I tried many distortions to the classic "W" geometry. I tried pointing it slightly upward and downward. Its like a treasure hunt to discover the magic combination. I have three conclusions to report at this time:

1) It seems the performance is vastly improved if you feed the antenna below its resonant frequency. When I feed at resonance, the SWR is near 1:1, but the gain is only 7 to 8 db and the F/B is only 3 to 4 db. If I feed slightly above resonance, the SWR increases slightly, but the antenna becomes almost omni-diretional, like a vertical. Now here is the good news... If I lower my frequency about 200 to 300 Khz BELOW resonance, the SWR becomes 3 to 4, but the gain jumps to 12 db and the F/B jumps to 20 db+. I see this same effect on all my models, regardless of other factors. My conclusion is to always "under feed" a hex beam.

2) I tried to improve the vertical radiation angle by tilting the antenna slightly downward, and/or playing with sloping elements. It seems if you want a better angle for DX, you need the simply raise the antenna higher. Nothing else has much effect.

3) I tried various lengths for the reflector. If I make it too long, there are two dips in the SWR curve and the overall performance is not good. If I make the reflector identical to the driven, it still reflects very well, but the bandwidth is slighly narrower. I tried to force it to act as director by making it even shorter, but no way. It won't act as director no matter what I do. If I leave a large gap say 2 to 5 feet between the two W's I get better gain and F/B ratios.

3284. Hexbeam Model

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-07-26 23:21:48 UTC
From: w4wb
Topic: 3284 Message: 3284

Hi Doug,

Sounds like you have been having way too much fun!

Traffie has made hundreds of HBs over the years and has climb up and down the towers several thousand times he has told me. I know for a fact that when he was developing the 30-40 m Hexbeam for me a couple of years ago, he/we ran into a great surprise! The 40 m monoband was normal enough to do (only a handful have ever been made), but then Mike suggested to me that 30 m be added if I didn't care ... like who wouldn't want another band, right? Well, what we thought would be maybe a few days of effort to get it right, turned into many months more effort. Not continuous, but included head scratching time too.

One thing you notice is that you don't want to be right at resonance. The optimum is when the SWR is about 1.4:1 (about 35 ohms). The SWR rises rapidly at the low end and slowly as you go up. Best performance (gain and SWR) is between the min. SWR and the fast rising region ... not an overly wide spectrum.

Back to the 30-40 m HB ... after he got what seemed to be a "hot-to-trot" tuning for the phone band (feed for this one is better from bottom rather than top), I reminded him that I'm really more interested in CW operation on 40 m than phone. No problem, right? Wrong. Trying to do the standard retune of the elment to slide down about 150 kHz proved to be a true head scratcher. The antenna performance just fell apart going to CW. Bummer. He had never seen this before on the higher band HBs. Anyway, after a bunch more testing and experimentation, he got it to work and does it work well!

I also note that the TOA is lower than you find with a NEC model. Best I can figure out, this has to do with NEC not accounting for the incident field on the 3 other sections of the driven element from each segment on the other portion of the driven element. On receive, it is better. Actual probe measurements have demonstrated this.

In any case, Traffie has developed a solid understanding of what make his antenna really sing.

73,
Barry W4WB

Doug,

FWIW, attempts to follow the balum path have been tried by Traffie and others, but were found not to work nearly as well as the feed method he uses for the commerical version. But maybe you are more clever in implementing the balun and can achieve improved performance. It would be most welcome I'm sure.

Hello Doug,
try your antenna SWR with a 25 Ohm feedpoint resistance and you will
get gain and good SWR together. For a monoband version I suggest
this. Feeding is easy via a 1/4 wave coax stub.
This is know from other 2 element beams (X-beam, reflected M) as well.
If you go for a multiband version with a common feedline you have to
make some compromises in performance if you like to feed all bands
together.
This is what you found out.

Barry:
Regarding the 30/40m version I had a lot of modelling to do as well.
And the best results where far out of sometimes published relations
for elements and insulators.

I wonder why Traffie again is feeding the beam from the top. I cannot
see any advantage for this. There is no better gain or easier
handling etc. All my beams are fed at the bottom element (20m+ and
40m+ designs). I have published the design for a 30/40m beam about
2.5 years ago from now. So he could start his beam based on this.

Subject: [hex-beam] Toroids for HexBeam and RFI Suppressions

Just got in some of the very best extra heavy duty toroids usable in RFI suppressions. These are snap-on ferrite toroids. They fit very well over 9913 or RG8 type coax. Other sizes are also available.
Anyone interested e-mail me directly for picture and more infos.

Tom,
I got just what you're looking for. I have them in three different sizes. Attached is a picture.
The small one fits well over the RG-59 type cable. The mid size (middle one) fits snuggly over the RG-8U or 9913 type coax and the large one fits loosely over the RG-8U or 9913 coax. The large one has the most core and suppresses the most.
Price is $1.50/small, $1.85/mid, $2.65/large.
Lots of people bought the mid size ones to use as RF choke on the HexBeam. Any of them can suppress and eliminate the RFI problem that you have, just depends on what you need.

Traffie feeds from the top probably to maximize 20 meter performance on his 5 bander..,,,The reality check here is that if you add the length of the feed to your element lengths you get full sized dipoles. If you allow the parallel line feeds to be part of the antenna, they have little actual use other than feed.. THEY HAVE NO CAPTURE EFFECT...and little radition...Feed at bottom maxes 10 meters..Feed at top maxes longest band,,,

I have been reading the posts on here for a few weeks now. I ordered and received 6-13 foot black widow poles from Cabelas and plan to try the K4KIO design. I will remove the smallest piece from each pole which will give me 6-10 foot poles to work with.

Here is my quandry. I don't which design to work with. I am leaning toward the K4KIO design, but have studied W1GQL design also. I like how the latter leaves the nylon cord in place. Leaving nylon cord in place will keep the soft drawn copper from stretching. Doesn't nylon also stretch? I have some left over surplus parachute cord laying around which has been guying push up masts now for 3 years without much stretching. HRO sells black dacron locally.

Also I don't know whether to start with a single band version or opt for multi-band at the start. My current interest is 20 meters with 17 as a possiblity. But I am sure the wire dimensions and loading change as the number bands change. I have an extra 30 foot push mast. So the height will be about 30 depending on the actual length.

Well I am off the local hardware store now to look for parts.

73,

Steve N6VL

Steve --

Having just completed my construction about a month ago, I'll give you my opinions based on my experience.

For the most part, I followed Leo's (K4KIO) design and construction approach. Instead of the cutting board baseplate, however, I used wood and painted it with several coats of Rust-O-Leum paint.

I ended up only stringing 20M/17M/15M, but have the cut elements and could add them later on.

I used Nylon cords each 9'5" in length -- 12 in total -- and ended up leaving them all in place.

Top feeding at the 20M elements worked best for me. I have very good and very flat SWR readings across 20M, higher on 17M an 15M.

I have not noticed stretching of the nylon cord beyond the initial "give" that you get from pulling things taught. You really can not (at least I could not) fully appreciate just how delicate the adjustments are. The wires are not stretched very taught -- if the wires are taught, then the cords lose their tension. It is also very easy to pull the poles out of shape. It is very much a labor intensive effort and plan to take your time.

In fact, I found it very useful to do a little bit at a time, then leave the antenna over nite before working on it more.

The antenna is now mounted on a pole about 20' in the air. 20M is working GREAT -- I'm only running 50W and am getting fantastic reports from throughput Europe. I'm very much impressed.

Send me an email address and I'll gladly share some pictures and more experiences with you.

Good Luck !!!

3296. Preventing pressure treated plywood from warping

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-08-09 20:29:18 UTC
From: Mark
Topic: 3296 Message: 3296

In preparation of moving my short tower (its only temporarily installed) I've taken it and my hexbeam down. The 1/2 inch plywood hub has warped which appears mostly from the tension on the fiberglass spreaders which are heavy duty ones from Max-Gain Systems.

However, it may have just been the glue's exposure to the elements.

Does anybody know if sealing the pressure treated plywood would have made any difference?

In the mean time I am preparing a new hub using K4KIO's cutting board idea.

3297. Spreaders - How small is too small?

Yahoo group: hex-beam (2001 — 2006)

From: JT Croteau
Topic: 3297 Message: 3297

I've been studying Hex Beams for several weeks and finalizing my plans for my first build.

My goals for this antenna is a quad bander for 20/15/10/6. I don't have an HF rig that covers the WARC bands at the moment and don't see one in my shack in the near future. I'd like to make this as light weight as possible and exploring various plastic materials for this project.

For the spreaders, I am thinking of coming off of the base with 3' of 1/2" fiberglass tube with 1' of solid 1/4" rod stuck in the end to give me a solid 1/2" to clamp down on at the base. The rest of the spreader would be 1/4" solid fiberglass rod with 7' exposed after sticking 1' into the 1/2" section.

Now, my question is, am I thinking too small? I'm not really sure because this has to be at least as strong, if not stronger, than using crappie poles everyone is using. But most of the guys using fiberglass spreaders are using larger spreaders originally made for quads.

Unless I can find a bulk deal on eBay for 13' crappie rods, I can't justify the cost of ~$65 + shipping for a set of six crappie rods. I am local to Max-Gain Systems where I can get more than enough material for ~$45 + tax for my 1/4" x 1/2" spreaders.

I'd appreciate input from those who have homebrewed hex's.

Thanks

I found 4' lengths of 3/8" diameter fiberglass rod at my local Tractor Supply store. They are sold as electric fence posts. I could wish for longer heavier rod but the 4 foot 3/8 inch are what the local Southern Oklahoma farm stores are stocking. I built my 20 meter monoband hex beam using this material. It worked but I believe a bit heavier rod would have improved it. Best thing about the posts I used was the price, 99 cents per post. I used info from W1GQLs Hexbeam website to construct my antenna. When I advised him of this fence post material he checked (I believe he said they were Agway stores) in his area of New England and found 6 foot lengths and 1/2" diameter posts being sold. Wish my local stores carried this size. If you are so fortunate as to find the heavier electric fence posts in your own home area farm stores I think you'll find them useful.

JT:
I bought my spreaders from Max-Gain. I bought 3 8' pieces of 3/4" tubing and 6 pieces of 1/2" tubing. I cut the 3/4" pieces into 4' sections and slipped the 1/2" pieces into the 3/4" sections till the length was right. Once the length is right the rest falls into place nicely.

I first tried a tapering combination of 3/4" tube to 1/2" tube to 1/4" rod for a 5 bander but found the 1/4" rod too flexible. With a 4' length it didn't have the tension to hold the 20m wires tight. I ended up going with 8' of 1/2" to the tips. See http://www.zievid.com/W6OT/Hex/Beam.htm for more info. All material was from Max-Gain.

I think it would work with all 1/2" tubing, but I haven't tried it. Adding the reinforcement at the base under the clamps is a good idea.

Thanks Dave and all others who replied.

I am leaning towards 8' of 1/2" solid to the tips based on some of the experiences I've read. The rest of the length will be 3/4" with 1/2" solid in the 3/4" where it gets clamped down onto the base.

Now, my other question is, what is the easiest way to draw out the hex base so I can get all the angles for the spreaders @ 60 degrees? I failed geometry bad. Actually, I dropped out of high school cause I was stubborn and lazy, but this is another story for another time.

Hi JT -

I haven't tried 1/2" solid rod, so if you're actually going to Max-Gain you might want to see how it flexes. You can probably save a few bucks and some weight by using the tubing.

To draw the base layout, I did it in pencil on a large sheet of paper. You can do it a few ways:

* Buy a cheapo protractor and mark lines 60 degrees apart. You only need 3 lines, since they run straight through the same center. So just use an edge to draw one line, mark the center point, then draw 2 more lines through the same point, all at a 60 degree angle. Then measure from the center as far out as you want and mark the edges where you'll cut.

* You can make a hex shape without a ruler if you have a compass (drawing gizmo with a pencil on one side, sharp point on the other). You can draw a hex shape based on the fact that all sides and the distances from the hex points to the center are the same. This is hard to describe, but try following these steps:
a) Draw a straight line at least as long as the base plate
b) Pick a point on the line for the center and mark it
c) Use the compass and draw a circle with it's center at this point (stick the pointy end of the compass there, and twirl the compass around dragging the pencil end on the paper). You'll now have a circle with a line through its center.
d) Put the sharp part of the compass at one point where the line and circle intersect, and draw another circle there.
e) Repeat that step for the other point where the first circle and line intersect. You'll now have 3 circles with a single line connecting their centers.

The points where the outer circles cross the inner circle line are the other 4 points of the hex.

I did the layout on a piece of paper, cut it out and traced onto plywood.

Hope I'm making sense,
- Dave

Actually, I'd save weight but pay more.. an interesting dilema.

1/2" Rod 1.22 lbs. $6.00/8 ft.
1/2" Tube 0.837 lbs. $6.50/8 ft.

I will probably go for the tube for that extra bit of weight savings.

My base plate is actually a perfect 12" x 12" square so I should be
able to draw a hex on this quite easy with a ruler and nice straight
edge.

Thanks again.

From: Colin
Topic: 3297 Message: 3304

Hi
Using 1/2" tube alone for the spreaders could create some problems.
They will tend to go "S" shaped very easily, especially on a 5
bander.
With very careful adjustment you can get them straight but they will
remain extremely flexible (both laterally and vertically)
On a windy day the spreaders can be pushed out of shape.
If the wires can move in relation to the attachment points (ie: by
sliding through the small tubes) the wire lengths will change .
The spreaders will be unable to recover the original shape as they
don`t have enough "spring" strength to pull the wire back to where it
started.
Clamping the elements to the spreaders at the attachment points so
they can`t slide may be a good way to prevent this problem.

Also be aware that the center post will need to be somewhat longer
than usual as the 20m element will start higher up the post due to
the bend of the spreaders.
Overall, using 1/2" may seem like a good idea for economy but a
larger diameter would be less problematic.

Good luck with your hex
73

3305. Wideband feed system?

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-08-14 19:19:10 UTC
From: steveeh131047
Topic: 3305 Message: 3305

Hi Folks,

I'm a new boy to the group from England, but have been "playing" with 20m HexBeam designs using EZNEC for a couple of months. I found that the gain and F/B performance is generally quite narrowband, but if I feed both the Driver and Reflector it becomes much more broadband.

For example, using DL7IO's single-band 20m model the Free Space gain and F/B fall from 5.5dBi/15dB at 14MHz to 3.3dBi/5dB at 14.4MHz. But if I then feed the Reflector in addition to the Driver (with a "reversal") the gain and F/B are much more "stable". Between 14.1MHz and 14.7MHz the gain increases steadily from 5.3dBi to 5.7dBi and the F/B increases from 9.6dB up to a max of 15dB (at 14.4MHz) and then back to 9.7dB. Clearly, the antenna dimensions could be scaled to centre this performance on the 20m band.

Like most 2 element driven arrays the feedpoint impedance is pretty low. Between 14.1MHz and 14.7MHz the Real part is stable at 8 to 9 Ohms, and the reactance increases from +10 to +34 Ohms. I'll leave it to others to work out how to match this to 50 Ohms:)

The same technique works with other HexBeam models (e.g. Cebik's), and indeed with other beam types.

I thought some of the Group might be interested in these results - I'm new to EZNEC so I hope they are "real" and not a modelling aberration! It might be interesting for someone with a real antenna to try it out - looking at the way most folk construct the beam it would be a relatively easy change to make.

I've found the Group an excellent source of info - thanks.

Steve

3306. Anyone built a 10 - 40m version?

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-08-18 05:53:35 UTC
From: slolawfirm
Topic: 3306 Message: 3306

Hi Folks,

I am considering building a 5 band version; I may have the room to extend the spreaders sufficiently to add 40m (although not sure it would be mechanically stable, among other things.) This would allow my removing of all the other antennas in the yard.

Regards,

Phil KM6CZ

3307. Re: Wideband feed system?

From: steveeh131047
Topic: 3305 Message: 3307

I've done a bit more modelling work since the first posting. I've scaled the dimensions to centre the performance on 14.2MHz, and matched the feedpoint impedance with a simple 45 inch length of 12.5 Ohm line (4x50 Ohm lengths in parallel). Modelled Free Space performance then is:

Freq Gain F/B SWR
14.0 5.3dBi 12.5dB 2.0
14.1 5.4dBi 16.0dB 1.4
14.2 5.4dBi 18.3dB 1.5
14.3 5.5dBi 15.6dB 2.1
14.35 5.5dBi 14.0dB 2.7

The drive to the reflector is modelled as a very short length of reversed transmission line. If I model it by connecting the right-side of the Reflector to the left-side of the Driven element & vice-versa I get very similar results. I'm happy to post the EZNEC file if anyone is interested.

Just collecting together the bits and pieces to make myself a 5 bander so that I can join in the fun!

Hi Steve,

I wonder if you have tried to compare your modeled results against Traffie's measured results. See
http://www.hexbeam.com/performance.shtml
FWIW, my SWR and F/B measured values are essentially the same as he reports. At my QTH, I don't have an appropriate setup to measure the gain independently.

Note also that his gain is reported in dBd rather than in dBi as you have below, so the dBi = dBd + 2.15 dB. Also, notice carefully the behavior of the SWR and F/B vs. frequency. I have observe the same on several of the Traffie-made Hex-Beams I have measured. I mention these points Steve since I notice the significant difference between your values and his.

Have fun modeling!

3309. The Traffie HEX-PAC

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-08-19 11:29:51 UTC
From: w4wb
Topic: 3309 Message: 3309

I recently received the Traffie HEX-PAC after finally getting enough coins in the cookie jar. http://www.hexbeam.com/hxp.shtml

First impression is simply great. A couple of my ham friends were there when I opened up the box and we all commented on the quality of the HEX-PAC. Perhaps the best way to describe the HEX-PAC is that it is a portable Hex-Beam system to construct monoband Hex-Beams. Mine configuration covers six bands (6-20 m). The HEX-PAC contains a number of color-coded arms that you select the proper collection to construct whatever monobander you which to use. Sort of the ultimate "tinker-toy" antenna set. All of the items you need for all of the antennas are packaged in a well-made and well-configured custom tote bag that travels easy. Weight is only 13 pounds.

I had my HEX-PAC "modified" a bit in that rather than just having 6 sets of elements, each tuned to cover all of the appropriate bands, I had 3 more sets of elements included specifically tuned for the SSB band segments on 10, 15, and 20 m. Due to the behavior of a well-tuned Hex-Beam, it does make a difference in performance when you really want to be competitive. I have two sets of elements for 40 m for my 40-30 m Hex-Beam and, yes, it does make a difference. My 5-band Hex-Beam has all of its elements tuned for CW (where I often operate) and I simply take the performance decrease in the phone bands; however, it still performs adequately well to be quite competitive in the phone bands.

As soon as I have a little free time, I will try out the HEX-PAC on the air. I recently acquired a BlueSky Mast system that has a 15 m capability. With this system, the Hex-Beam can be raised to 50 feet by one person in about 15 minutes, and in about 8 minutes with two people. This is a military-grade mast system. If interested, see www.blueskymast.com.

Now off to the Huntsville Hamfest for the day!

Hi Phil
I can`t quite fit a 40m hex here, so i`m stuck with multiple antennas. It does makes sense to compact as many bands into one antenna if you can, economical too with a single support structure.

Considering the stability aspect,the basic format of 6 flexible spreaders is great.. if you can find ones with the right properties at the correct length (and reasonably priced!).

I am looking into alternatives that may provide the correct curve and rigidity without relying on expensive fibreglass tube, which as we all know, accounts for most of the antenna`s cost.. whether commercial or homebrew.

It may even make 1/4" diameter spreaders a viable option :)

Best of luck with the big 5 bander

Hi Barry,

Yes, I have compared my modelled results with the Traffie figures and noted the differences.

In fact, my interest in "playing" with Hexbeam models started because none of the published models I could find (DL7IO, LB Cebik etc) seemed to produce results close to Mike's figures across the whole of the 20m band, and I wondered if I could do better ..... the answer appears to be no :(

I wonder if anyone out there has an EZNEC model that gets close to Mike's figures?

Please don't think I'm callenging Mike's figures - I think Mike's design is innovative and I can't wait to build a "real" one of my own. Just waiting for the poles to arrive ... !

Hi Steve,

I understand and I find it interesting that you are investigating a means to broaden the bandwidth. One way might be to use heavier gage wire and (for a monobander) use a pair of such wires spaced apart. This technique is used with dipoles.

It is my opinion that NEC doesn't properly allow modeling of the Hex-Beam in its transmit mode, although it is closer to reality in the receive mode. Nevertheless, it is fun to play with models and gain some nice insight. FWIW, Traffie published the basic configuration equations in a paper entitled "Miniaturized Antennas" in 1995. This is located in the Publications Folder in the Files section. Over the past decade, Traffie has refined his tunings and configurations from the practical knowledge gained in building hundreds and hundreds of Hex-Beams, which he checks each one fully deployed on a test tower before shipping to the customer. A somewhat remarkable characteristic of the Hex-Beam is that even when it is not optimally tuned, it still performs rather adequately; however, when it is really tuned up, the antenna truly "sings!" :-)

Hope your attempt to build the antenna is highly successful!

Hi Ralph,

I have posted the EZNEC file in the "Files" area under the name "20m Hex 2 elements driven".

The dimensions are pretty much those of DL7IO's single band model. In addition the model contains 2 transmission lines:

Line 1 is just a convenient way to model the drive to the reflector. Note that it is "reversed" i.e. right side of Driven element connects to left side of Reflector & vice-versa. The Zo of the line, and its length, are not at all critical and in practice you would simply connect the antenna wires together.

Line 2 is a simple series-section to match the low feedpoint impedance to 50 Ohms. The Zo here and the length are of course important.

I found the rather large number of segments to be necessary on most Hexbeam models in order to reduce the "average gain" figure to something acceptable.

I've done no work at all applying this technique to multiband models.

I guess one way of viewing the antenna is to think of it as a a "ZL special" with bent elements, and in which the proximity of the 2 drive points leaves no room for the phasing line!! The element current phasing necessary to achieve directivity is achieved solely by the different complex impedances of the 2 drive points.

Okay guys here ia a crazy idea...Broad band it by using twin lead for the elements instead of wire...NO I haven't tried it YET...I bet if you make one of the twin lead wires shorter than the other it could work! Its a good experiment to try...We have been doing it with dipoles for years..The deminsions will be just a bit shorter also due ti the linear loading provided...Out to the lab for some fun!!!..W4HV Mike

Hi Steve
Sounds like this might be a good candidate for a folded dipole driven
element.
The 12.4 ohms would be transformed (4:1) to almost a perfect 50
ohm ;)

Topic: 3305 Message: 3318

Hi Colin,

Thanks for the suggestion.

Unfortunately the feedpoint impedance is not 12.4 Ohms - mid-band it is about 7+j20 so folding the element wont produce a 50 Ohm match; however a series section of 12.5 Ohm transmission line works just fine :)

3319. Dimensions of Traffie Five band hexbeam

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-08-20 18:53:45 UTC
From: k4kio
Topic: 3319 Message: 3319

Does anyone have the wire lengths and end spacing for the elements of the Traffie Five Band Hexbeam?

Thanks,

Leo, K4KIO

3320. Chimney mount?

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-08-20 22:36:10 UTC
From: kc0rdg
Topic: 3320 Message: 3320

I am wondering if it would be possible to use a chimney as a mount for the Hexbeam.

I would use a chimney mount kit from Radio Shack, attach a pipe to it and secure the bottom of the pipe to the roof then mount the rotor and Hexbeam on top. I know it doesn't weigh much so I was wondering if this would be a safe alternative for the meantime until I get a pushup mast up. The pipe would extend maybe 3 feet above the chimney.

I have a small picture (unfortunately) of my house and you can see the chimney a little bit on top http://tinyurl.com/jf5hr

Thanks

Hi their
I mounted a anttena to my chimney with preaty good results. I mounted a spider beam with just the set up you talked about. When I frist put it up I did not use any kind of roof mount. I just had the pole held up by the chemney straps. The antenna only ways about 12 LBs, but the frist wind that came along made the anttena come down and rest on the roof. I then redid everthing and used a roof mount to hold the bottom of the pole. I also added guy wires to make sure that everything stayed up. I worked very good for me. I had the beam up about 37 to 40 feet from the goound and about 15 feet from the roof. Made lots of contacts and even was able to make contacts with a lot of DX with good results. All of this with just 100w. So I guess that the reason for this story is to say yes, put that antenna on the roof and start with the "hamming".

Have you considered putting the rotor at the bottom of the mast? Check out ve3efc's neat installation - http://ve3efc.ca/hexbeam.html. Note especially the picture at the bottom of the page.

I installed my hexbeam on a push up mast with a radio shack rotator at the bottom per Mike Traffie's suggestions. There are a couple of pictures in the group pictures section.

The idea is to minimize the wind loading as much as possible.

Good luck,

Michael kd5wby

Interesting. I cannot tell from the pictures how he secured the wood to the chimney. It would appear that this is something I can do. Having the rotor turn the mast and antenna might be good from a wind load perspective. I am planning on purchasing the Yaesu 450 rotor which I think should be enough for this application. I looked into the past posts and I have found a couple of them relating to mounting it on your chimney, so it would appear this is a viable alternative with the biggest drawback being the height above ground. It would be higher with a (pushup)mast but that involves more $.

3324. Use of insulated wire

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-08-23 23:36:50 UTC
From: slolawfirm
Topic: 3324 Message: 3324

Hi folks,

I would like to use insulated wire for my home built hex beam. I recognize this will add a few pounds of weight which isn't a problem. However, I am wondering whether the velocity factor would be changed as a result or otherwise change the dimensions provided by the pioneers of the homebuilt HEX beams.

Any thoughts?

Regards,

Phil KM6CZ

Phil, he can speak for himself if he happens to see your posting but Holger says that you will need to reduce your wire lengths if you use insulated wire. See his pdf presentation, page 10.

My first Hexbeam used insulated wire, the calculated velocity factor of the wire was different to the actual velocity factor, in the end the lengths were about 1% out. The problem was that I had perfect 1:1 SWR on all five bands but no front to back and actually negative front to back on 12m. I replaced it with bare wire and have been happy ever since.

So, only use insulated wire if you know the 'actual' velocity factor.

Phil,

Insulated wire will indeed have a velocity factor - between 0.99 and 0.95 according to LB Cebik - depending on the type of insulation and its thickness. See http://www.cebik.com/amod/amod50.html for more details.

I would suggest that you first build just the Driven element to published dimensions, and check its resonant frequency - it will be too low. You can then calculate the velocity factor from the ratio between the actual resonant frequency and the "intended" one. Then you can simply scale all your element lengths (including of course the reflectors) by the same amount.

Good luck,
Steve G3TXQ

3328. Re: Use of insulated wire & an idea

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-08-24 20:47:14 UTC
From: slolawfirm
Topic: 3324 Message: 3328

Thanks to all that replied. I think I will save myself the effort and just use bare copper wire.

There was an article on ham universe describing a 17m coaxial hybrid hexbeam which used RG-58 (vf of 0.66). Based on one of the other poster's spreadsheet, a 40m beam using RG-58 for the elements should fit on a 12' spreader. (I actually built the 17m hybrid hex antenna and it worked great until the bamboo spreaders broke!)

This may allow all bands between 40 - 10m on a hexbeam not much larger than the standard 5 band version (albeit, alot of interaction to deal with.)

This technique might be useful to reduce the standard size of the 5 bander down by about 33%.

Has anyone tried this in a true hex configuration?

73's

Phil

Phil,

The weight of the RG-58 might be an issue, depending on how strong your spreader poles are.

I wonder, too, if the coax might introduce losses - it certainly isn't operating under matched conditions, and presumably suffers quite high equivalent SWRs at different points along its length.

I'd be interested to hear if anyone has done any work on this - for Hexbeams or any other antenna. I've not seen any published data and as Phil says, superficially at least it looks like an attractive way of reducing significantly the size of any wire antenna.

73,
Steve G3TXQ

From: slolawfirm
Topic: 3330 Message: 3330

Here is the link to the 17m hybred antenna I mentioned eariler. The author calls this a moxon, but it is actually closer to a hex beam configuration.

http://www.hamuniverse.com/17mcoaxmox.html

I've actually built and used this antenna and it worked fine. The only problem encountered was the cheap bamboo did not last more than a couple of months in the California sunshine. I plan on incorporating this idea when I actually get time to build the hex beam. I don't believe the weight will be a problem; finding the proper position and tuning may be difficult.

Hi Doug,

Good to see interest in the HXCC award.
Thunderstorms and lightning here today, so getting an opening.. doth
not bode well hi.
None the less, we can live in hope and i will be around on 20m about
21.30 (UTC) tonight.

If anyone else is interested in the HXCC award, I usually monitor 17m
(18.130) 13:00-14:30 utc most afternoons.
I`ll probably be that real weak station you hear with only 20w-30w ..
but I`ll be more than happy to give you a point.

Hi Ion
I like the hub idea, looks like a lot of work compared to a plate.

I can`t help but think those rods will cause the most problems in the long term.
The surface finish of the rods tends flake from uv,wind and rain etc after a year or so of exposure, which can look unsightly so you might need to consider some form of coating.

The other thing apart from the strength of thin wall of fishing poles is the thermal expansion properties of all the different materials involved.. fibreglass, aluminium, stainless steel etc.

With the normal hubplate there is a certain amount of buffering between plate,u-bolts and spreaders afforded by the short pvc tube sections.

It may not be an issue, but it seems to me if the rods are only eg: 0.5mm wall thickness, it won`t take much expansion to crack it, especially when under tension.

$500 is a good price compared to a genuine hexbeam.
If they both have the same maintenance requirements and longevity,it`s a real bargain. Without proper testing ,(perhaps, a year or so on a mast)it would be hard to predict with any certainty.

Has anybody used FLEXWEAVE□ 14 AWG with Black Polyethylene jacket
for their antenna. I am looking into using this for the Quick Hex
Beam. What is the velocity factor for that? I will do my own
testing with it, but a little bit of info would help.
Thanks

Hello, I am thinking about getting and installing Traffie's HDX pushup mast with the rotor at the bottom to turn the whole mast and Hex-beam. I plan to make it a semi-permanent installation as well by using Dacron rope with 770# strength. What I would like to hear from anyone who has the HDX mast how you like it and how it is holding up, etc. Please reply directly to me at w5rae@... <mailto:w5rae@...> rather than back through the group. I have used the same rods before without any problems. They have been up at 30feet for over a year now, and they hold up to some 50+mph winds. One of these days I'll take the beam down and take some pictures of the rods just to show people how the held up. I'll post them on my web site.

I've used the Traffie HDX pushup in the configuration you've described for over 4 years with no problems. Just to be safe, I replaced the guy rope after 3 yrs and I also drilled a hole in the antenna hub to mast to secure the antenna (maybe Traffie predrills a hole at the top of his HDX masts now?). Hi Ion,
I`ve used them for quad spreaders and they performed quite well using the thickest parts of the rods, but in the case of a hex they will have to bend.

You mentioned you are using 11ft of a 16ft rod.
Over here the 5m (16ft)rod has a base section diameter of about 30mm, When you try to bend the rod to the correct curvature ..the chances are it will break. I haven`t managed to bend a 5m rod in the way you describe without failure..hence i switched to much stronger fibreglass tubes for the hex.

If you use the 2nd section as the largest size it should be ok, in which case you might as well use a 4m rod with the top removed, the spreader will be less rigid and smaller diameter at the tip.

You mention you already have a beam up using the rods, is it a 5 band hex or one that uses the rods as straight spreaders as in a quad or monoband hex?

3351. Hexbeam photos

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-09-05 18:15:40 UTC
From: steveeh131047
Topic: 3351 Message: 3351

Hi Folks,

I've posted some photos of my "build" under "G3TXQ's HexBeam". There are one or two new ideas:
1) The bottom 12 inches of the centre post are reinforced with thickwall aluminium which is tapped to take the bracket bolts
2) Spreader supports are aluminium angle and tie-wraps .... only time will tell if they're strong enough.
3) I used plastic "wall plugs" glued into the end of the spreaders to provide end supports.

73,
Steve G3TXQ

Looks like you did a great job, Steve

It`s always interesting to see the different approaches used by homebrew hexbeam builders :)

The centerpost feed and element attachment methods are perhaps the most varied.
I came up with a few new ideas after some initial designs failed to make the grade,which may (or may not) be useful.
M6 brass dome nuts (with a hole drilled in the middle) are great for "inline" element attachment (no soldering required)

M6 brass bolts with heavy braided wire (4mm dia) makes a great feedline down the inside of the post (soldered to bolt heads)
http://usera.imagecave.com/djcol/Hexbeam/feedsystem1.jpg
http://usera.imagecave.com/djcol/Hexbeam/centerpost.jpg

The best method i`ve found so far for element to spreader attachment is very cheap and has minimal metal in the vicinity of the elements.
Assembly joints from "Wilko", 24 for under £2
M3.5 x 40mm nickel plated brass bolts, normally used for fixing lightswitch pattress to backing boxes, 1000 for £5 from electrical wholesalers, a bag of M3.5 brass nuts completes the job.

http://usera.imagecave.com/djcol/Hexbeam/elementtospreaderconnection.jpg
http://usera.imagecave.com/djcol/Hexbeam/AssemblyJoint.jpg

I`m sure your hexbeam will hold up to the good old British weather very well.
Have you had a chance to test the performance yet?

Colin,

Thanks for the comments and the new ideas!

I've done some polar plots on all bands with a local amateur, and I've also "swung the beam" with a DL and a WD8 on 20m. They reported encouragingly high F/Bs of about 4 'S' points - in the case of the WD8 on a calibrated S meter (6dB per point). Results with the local amateur were more modest (between 1 and 3 S points) and more what I would have expected.

I have been working on a paper containing HexBeam modelling data, and some practical measurements on my beam, which K4KIO has kindly agreed to publish on his web site ..... watch this space for an announcement!

3354. Understanding the HexBeam

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-09-07 08:20:33 UTC
From: steveeh131047
Topic: 3354 Message: 3354

Folks,

During the course of designing and constructing my HexBeam I carried out many hours of EZNEC simulation and made lots of practical measurements. This gave me an insight into the beam which I thought might be of interest to others.

Leo (K4KIO) has kindly turned my efforts into webpages which can be found at:

http://leoshoemaker.com/G3TXQhexbeam1.html

Our intention is to provide a link to this material from Leo's main site, thereby making it widely available; but before doing so we thought it prudent to offer it up to this group for review.

We're particularly interested to hear of any technical inaccuracies that it might contain. So please have a look at the material and E mail any comments to me at hexbeam@...

Thanks for your help.

Steve G3TXQ

Shame on me, I discovered very recently and it seems to correspond exactly to what I am looking for.

- no trap
- lightweight (can be mount on a mast with small rotator)
- highly resistive (wind, corrosion, ice and any bad weather condx)
- covers at least 5 bands from 10 thru 20m
- discret but fire up the sky for DX
- only one cable to feed the 5 bands

I live in Paris city and my roof is 35m up with a very good opening, all around 360°

Unfortunately, some workers are rebuilding entirely my roof's waterproofing and they plan to finish by the end of year.

I think I will purchase a Traffie HexBeam, but the price is very very high, especially there is shipping, and a lot of taxes (about 28%) to get it in France.

We have a secondary house, in Normandy, and I plan to build an HexBeam for our /P QTH.

I found good ideas on DL7IO, K4KIO, and a few others and I still need to check it carefully, but the project could be fun, and economic.

Of course the problem is to find/build all the necessary parts, especially the fiberglass tubes (at a good price) and the mounting plate.

If you have any advices, they will be more welcome here.

I need to confirm but I think a UK friend of mine, gave me an address in England and the price for 6 fiberglass tubes of 4 m will be only €65 (but I need to confirm it).

Hope to read from you, and I have the great wish to become a HexBeam user, before long.

73,
Steph, F5NZY

Gene,

I used 4 metre (13ft) telescopic fishing poles obtained from an angling shop. These come in 4 sections, but you need to discard the end section because it is too flexible. The remaining 3 sections extend to about 10ft which is the minimum you need for a 20m capability.

I found some of my poles were shorter than others by up to 4 inches so it pays to check them carefully. If you use the sort of arrangement that I, or K4KIO, have used you gain a bit of length because the poles are held "outboard" of the baseplate.

The particular poles I used are made by a company called Shakespeare and their part number is 1056-400. I'm not sure whether they are available in the USA. You can take a look at one on the website of the UK shop I bought them from:

http://www.moefish.co.uk/

They are not expensive - 4.99 UK Pounds

I bought one pole first to check that it had the right amount of "bend" and only bought the others when I was happy! I didn't start drilling holes in the centre post until I had the "geometry" right and knew exactly at what height the various band elements would sit. I can heartily recommend K4KIO's method of "stringing" the framework - it worked a treat and I was able to do it single-handedly - no need to involve the XYL !!

Good luck,

Steve G3TXQ

Hi Steph,

you can purchase fishing rods at Decathlon in France
and often at Casino, Carrefur and Auchan hypermarkets.

Fpor the Hex-beam you will need topurchase the 5
meters lenght and remove the top meter.

3359. longer haul dx

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-09-14 16:48:39 UTC
From: Colin
Topic: 3359 Message: 3359

The hexbeam never ceases to amaze me, especially on the
longer haul dx.

I worked a JA station around lunchtime today on 17m with a 5/8 report
using just 50w. He was using a 4 ele monoband yagi and a kilowatt.

The hex is just 11ft high to the 20m element! and seems totally
oblivious to the fact that it shouldn`t be working dx too well.

Imho, given a very heavily compromised qth.. the hexbeam would be the
best antenna to put on the (probably really short) mast.

Wow! I love to hear these kinds of things! Posts such as yours, reviews on eHam and my QTH have me sold on the Hex. I would be interested in anyone elses experience with the Hexbeam, commerical or homebrew. I put an order in for one today. I cannot wait to put it up! I have passed the General written, just need to pass the code, and I'm at about 98% proficiency.

You're close enough, I arranged to take my code test when I was getting
about 95% on test QSOs. Took the Gen'l written the same night and
passed'em both. My license upgrade to General was official as of 5-13-05
(a friday the thirteenth by the way). GOOD LUCK! If the code test is
finally set aside having actually passed one will have a certain
prestige value (course we don't really care about that, do we?)

Hi Elijah,

I believe commercial hexbeams are fully tested before dispatch so it should give optimum performance.

Mine is a homebrew, so it`s likely to be somewhat less than perfectly tuned.

Here`s a pic of the actual height of my hex to give you some idea of just how low it is

http://www.nurl.us/32l

As you can see it`s pretty much the worst scenario imaginable hi

The Hex doesn`t seem to mind though 50w = 6000 miles with a 5-8 report from Mako (JA2TQZ) isn`t too shabby considering.

Look forward to hearing you on 17m

Colin,

At that height you might really be able to convince the neighbours it's a rotary clothes line :) Mine's up at 20 feet and the XYL would struggle to reach it!

Only had mine up a couple of weeks but I've been having long "rag chews" with VKs the last couple of days on 20m, and on-air tests with VE7 and VE1 have shown very encouraging F/B ratios close to 20dB.

Tim,

If you take the dimensions for the dual bander from Holger's EZNEC files, just be aware that the interconnecting feedline is modelled as HIGH impedance (somewhere around 250 Ohms) - you will not get the same SWR results as Holger if you use 50 Ohm coax!

Hello,
2 wires with a big diameter installed very close together should
never give a high impedance line. It is thought as a low impedance
line and easier to handle than coax cable.
I have measured the impedances and they are around 50 Ohm.
If the feedline should be 250 Ohm in my 17/20m model than I have to
check this again. But to get 250 Ohm I would need 4 or more cm
distance between the proposed wire.

Holger,

Your17/20m EZNEC file models the interconnect as 4mm diameter wire with 9mm spacing. The standard formula for air spaced line gives Zo as 180 Ohms for these dimensions. To confirm this I removed all wire elements from your model, leaving just the interconnect structure, and then put various resistive loads at the opposite end to the source. A 240 Ohm load results in a 240 Ohm resistive impedance at the source end over a wide frequency range, so I assume this is the characteristic impedance of the line. I think the difference between 180 and 240 is explained by your structure widening out a little at the connecting points - this wider spacing would raise the impedance.

On your 20/17m model the 20m Driver is quite short and exhibits a large (typically -j20) capacitive reactance at 14MHz. For a reasonable match at the bottom feedpoint this requires the 400mm of interconnect to be HIGH impedance. My Smith chart calculations show that, for an impedance of 30-j25 (typical of your short Driver), 400mm of 25 Ohm line would result in a SWR of 2.6:1 at the bottom feedpoint; whereas 400mm of 240 Ohm line produces an SWR of 1.7:1, so I would expect the interconnect to have to be relatively high impedance.

I have done a lot of modelling of various interconnect impedances and feedpoints, and have concluded that Top Feeding with 50 Ohm interconnects is a good compromise. I hope to be putting a fuller explanation with supporting numbers into my "Understanding the Hexbeam" paper on Leo's Web site.

Apologies if I have misunderstood your model :)

Amazing! Seeing that and hearing your report makes me happy to know that I think I've made the best decision I could for my QTH. Can you imagine a dipole at that height?! Mine will be up at about 25 feet or so mounted to the chimney. I just have to come up with a way to attach the rotator/mast/etc.

Currently I am using a Inverted-L.. it doesn't work well at all. I hear alot of static and only strong stations. This is of course because I was not able to put down alot of radials. I will be glad to have a beam and glad to have an antenna that is not fed off ground.

In regards to the other gentleman about me being ready for the code test, I feel that I am almost there. Maybe I don't have alot of confidence in myself, maybe I just prepare for the worst. I do know that I get nervous testing! As it is now, I know most of the letters but sometimes after hearing so many, I get some mixed up - G and W, B and 6, K and R being my most troublesome right now. I want to be at the point when I hear a letter, I get it right the first time, everytime and am never confused!

Hello Steve,
I always worried about that there might be something wrong with my model but that the mistake is so simple is somehow infuriating...
Good to have you in the group and thank you for the advise! One sometimes gets unseeing simple mistakes.
Nevertheless this is a mistake and not a wanted special design.

I'm thinking with EZNEC the distance given is between the middle of the wires, so 4mm wire and 9mm distance between the middle is 5mm between the outer diameters. Therefore it has to be changed to +/- 0,0025 to have the correct dimensions and will of course result in other DE lenghts.
My plan was to leave 1mm distance between the copper for any kind of insulation. With the newer versions we should include the wire insulation into the model.

I think we have to recalculate a few of the models.

73 Holger

3372. Hexbeam grounding

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-09-16 20:38:12 UTC
From: obiwan9325
Topic: 3372 Message: 3372

I'm thinking of running a ground wire from the ground rod to one of the nuts on the base of the hexbeam. Has anyone used this method?
Any other suggestions?

3373. Re: Beam Specs.

Holger,

Don't feel bad about making a mistake. In England we have a saying "The person who never made a mistake never made anything!"

Keep up the good work ... it was your Website, and Leo K4KIO's, that encouraged me to build a HexBeam, and all my practical experiments show that the dimensions on your 5 band Top Fed design work very well.

I think you will struggle to model a really low impedance line with EZNEC, even with very close wires. The standard formula from the ARRL Antenna handbook gives:

Zo=276.log(b/a)

where b is the centre-to-centre spacing of the wires and a is the RADIUS of the wires. As you approach ZERO spacing, b approaches 2a and the impedance is Zo=276.log(2) = 83 Ohms - still quite high.

I guess that in practice your flat,wide, connectors with a dielectric insulator between them will probably have a low impedance, but as far as I know you cannot model this arrangement in EZNEC. For all my modelling I have used EZNEC's Transmission Line facility to represent the interconnections - this allows me to easily try the effect of different Zo's, including very low and very high values.

As I said in an earlier posting, I have found 50 Ohm coax to be a good compromise between two conflicting requirements. Let me try to explain why I think this is. Suppose we have a bottom fed, two band (20/10m) Hexbeam:

1) At 28MHz the 20m Driver will be high impedance and the interconnecting line will look like an open-circuit stub shunting the feedpoint. The lower the line impedance, the lower the capacitive reactance it represents and the worse will be the effect on the SWR at the feedpoint; so we should choose a HIGH impedance line.

2) At 14MHz the 10m Driver is high impedance and doesn't much affect the SWR at the feedpoint. However, the interconnecting line modifies the impedance of the 20m Driver as seen at the feedpoint, and high line impedances modify it most - creating high SWRs at the feedpoint; so we should choose a LOW impedance.

50 Ohms turns out to be a reasonable compromise.

We can also see from this example why Top Feeding has advantages. When Top Feeding, the "open circuit stub problem" occurs at 14MHz; when Bottom Feeding the problem occurs at 28MHz, and is worse because

the electrical length of the stub is double at 10m compared to 20m.
Or viewed another way - the stub represents a fixed capacitance
(typically 70pf) which has a greater effect at 28MHz than at 14MHz. I
have confirmed this with measurements on my four-bander; when I
bottom fed it I had very poor 10m SWRs - they improved considerably
when I top fed it.

73,
Steve G3TXQ

As the hexbeam has non metallic spreaders and centerpost you are really grounding just the mast.
You may as well attach it to the base of the mast and save some wire.
If the mast is in contact with the ground even that may be unnecessary.

To incorporate some lightning protection, a spark gap type arrestor in the coax line is probably the easiest option although in the unlikely event of a strike it`ll probably not be of much help hi

Why? At best the only thing you're "grounding" is the base plate.

If you want some degree of lightening protection (a) put a lightening arrestor (e.g., AlphaDelta TransiTrap) on your coax and ground that to the ground rod, and (b) do same with lightening arrestor (ICE and PolyPhaser) for your rotator cable.

If you want an RF ground for some purpose (a) it doesn't require one, and (b) given the probable length of ground wire from ground rod to base plate you're not going to have an effective ground.

So not sure what you're trying to accomplish.

Hi Steve,

thanks a lot for your very interesting and important comments.

Yes, Holger has done a really good work with theHex-Beam design.

I have started one year ago to put aside the various bits and pieces
to build my hex-beam with some personal mechanical differences..hi
The problem is that I have not found the time to assemble the
antenne...other priorities ... hi.

I am sure there are a lot of members like me waiting for your report.

In Italy too is valid the saying "The person who never made a
mistake never made anything!" ... I made no mistakes (yet) as I
built no Hex .... hi

Hi Steve,

I did use the data (wire and lenght) from DL7IO, the rings with the
feed system from ZS1WDK and the overal info from K4KIO.
Mine first attempt did go wrong because i did use to cheap fishing
poles and did not have the right wire.
But happy for me, on a ham market in Germany i did buy 250m from the
right wire for only 10 euro, which give me a lot of play ground.
In the first attempt the 50 MHz was much better than that it now is,
one of the reason can be that insulated wire was used.
Also is it so that i have the feeding point at the underside,
what perhaps the reason can be that 50 MHZ is now so bad.
Further investigation at my side must be done to solve this.
The first impression of this type antenna is above my expectation
and with more pleasure, also from the stations that i work.
As soon as i have more info i will let you now this.

Great antenna...
I worked several JA's on 17 1st call... I use my FT100 and 100 watts and they are running monobanders and 500 watts. and get the same report. Worked a C9 and S9
and many in South America and usually 1st call maybe a 2nd needed to get thru. It still amazes me how good the antenna works against someone with amps and bigger antennas. Worked a DL during the NAQP and he was 30 0ver 9. He had a stacked pair of 5 element monobanders and a KW and he had me 10 over with 100 so...I am in Idaho competing against the east cost..sooo I have been very pleased on how it works..
Hope to hear you all on..

kc0rdg <kc0rdg@...> wrote:
Amazing! Seeing that and hearing your report makes me happy to know that I think I've made the best decision I could for my QTH. Can you imagine a dipole at that height?! Mine will be up at about 25 feet or so mounted to the chimney. I just have to come up with a way to attach the rotator/mast/etc.

Currently I am using a Inverted-L.. it doesn't work well at all. I hear alot of static and only strong stations. This is of course because I was not able to put down alot of radials. I will be glad to have a beam and glad to have an antenna that is not fed off ground.

In regards to the other gentleman about me being ready for the code test, I feel that I am almost there. Maybe I don't have alot of confidence in myself, maybe I just prepare for the worst. I do know that I get nervous testing! As it is now, I know most of the letters but sometimes after hearing so many, I get some mixed up - G and W, B and 6, K and R being my most troublesome right now. I want to be at the point when I hear a letter, I get it right the first time, everytime and am never confused!

Hi Wim,

Sorry to prolong this, but ....

Holger has several different files on his website with varying dimensions depending on the feed arrangement. Can you confirm that you have used the dimensions in his .pdf file documenting the 5 band Top Feed design?

As you have discovered, you get a very high SWR on 50MHz if you Bottom Feed. This is because at 50MHz the feedpoint is shunted by a long electrical length of unterminated feedline - approaching Lambda/4. Assuming that the impedance of the interconnections is 50 Ohms, and that the total length from top to bottom of the beam is approximately 800mm (31.5"), this will be the equivalent of connecting a 200pF capacitor across your feedpoint at 50MHz - this would change a 1:1 SWR into a 12:1 SWR!!! The effect will be even worse if the impedance of your interconnecting line is lower than 50 Ohms.

Top feeding will cause the same effect to occur at 14 MHz, but the impact will be much less - the equivalent of an 80pF capacitor, which would change a 1:1 SWR into a 1.4:1 SWR

There will be a fuller explanation of this in my paper on Leo (K4KIO)'s website soon.

73,
Steve

Wim,

I forgot to mention in my last posting that Insulated wire, or wire
of a different guage, both change the frequency of the beam. It is
very important to get the Reflector resonant at your operating
frequency - the Driver is much less critical. I would recommend you
use a dip meter if you have one to check the 50MHz Reflector

Hi W4HV,

You raise an interesting issue.

What you say is true for "conventional" parasitic Yagis and quads, but not beams like the Hex where the element ends are very close together. In fact if you look at some VK2ABQ beam designs you'll see that the Driver and Reflector are the same length. In simple terms, designers are using the element end spacing as another design freedom in addition to (and sometimes as an alternative to) Reflector "detuning" and boom length.

If you need convincing by the maths, read Moxon's book "HF Antennas for all locations", chapter 5 on close spaced beams.

If you don't like the look of the maths (and I wouldn't blame you!) try running a HexBeam through something like EZNEC. Find the frequency of maximum F/B, find the frequency of maximum Reflector current, then remove the Driver wires and find the frequency where the Reflector is resonant.

Just did that myself:

Max F/B at 14.140 MHz
Max Reflector current at 14.120 MHz
Reflector resonance at 14.140 MHz

Do the same for a yagi and you'll find the Reflector is resonant well below the frequency of maximum F/B.

So ... really (for a HexBeam) it is!

73,
Steve G3TXQ

I agree that Moxons research agrees with you on close spacing..Espescially in models that are run in Ez , however putting the modeling down(which is programmed to reflect this phenomina)and actually building it I have found the parameter to continue to exhibit the other way ...Relector longer...Sometimes its in where you measure from and the type of feed used...End spacing and coupling of the elements can give a capacitive loading effect giving an apparent length change that is not actual as well...Its an interesting study!!!Glad to paticipate in it!

From: steveeh131047
Topic: 483 Message: 3386

Mike,

Thanks for that.

Just to clarify ... I'm not saying that the Reflector shouldn't be longer than the Driver. I'm simply saying that wherever the Reflector is self-resonant is where you'll get best F/B. That's what EZNEC says and that's what I found doing polar plots at different frequencies with a local Ham on my 4 bander.

I guess we can both at least agree that this is real interesting stuff!

Regards,
Steve G3TXQ

3387. 40 meter antenna

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-09-22 03:10:25 UTC
From: mherboltzheimer
Topic: 3387 Message: 3387

Can anyone tell me the price and size of the 40m version?

Thanks

Steve,

In Traffie's 1995 paper, it is evident that the reflector is longer
than the driven element as one should expect. I note that whenever
I forget which element is which when I have taken the antenna down
and then putting it up again, I can always tell the reflector from
the driven element by its longer length. EZNEC is fun and
instructive, but it doesn't really model this antenna correctly. A
nice feature is that it can be mistune some and still give
reasonable performance, but not optimal.

3389. Re: New file uploaded to hex-beam

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-09-22 07:51:03 UTC
From: steveeh131047
Topic: 483 Message: 3389

Barry,

Sorry to keep prolonging the discussion, but there seems to be a misunderstanding about what I am saying :)

I have NEVER said that the Reflector should not be longer than the Driver - it should be longer, and IS on all my EZNEC models and the real one that's sitting on top of my rotator. What I'm saying is: wherever the Reflector is resonant, that will be the frequency of best F/B. I'm not just claiming that on the basis of EZNEC, it was what I found in practice.

My interest in all this is to try to help people tune their beams. If you don't somehow get the Reflector tuned to the right Freq. you may be tempted to adjust the beam by tuning for best SWR. That's a recipe for poor performance as my notes on Leo's (K4KIO) Web site tries to explain.

Now I'll shut up and crawl back in my box :)

3390. Understanding the HexBeam

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-09-22 20:44:21 UTC
From: Leo Shoemaker
Topic: 3354 Message: 3390

If you are planning to build a hexbeam, are you puzzled as to whether to feed your hexbeam from the top or the bottom?

Should you use coax to connect between the bands or heavy wire?

And are you focused on getting low SWR, no matter what?

You might get some insight on these as well as other aspects of hexbeam design from Understanding the Hexbeam by G3TXQ. Steve has given me permission to add this fine piece of modeling work to my hexbeam website. You can check it out here.

73,

Leo, K4KIO

From: k4kio
Topic: 3391 Message: 3391

Sometimes, I wish interacting with the Yahoo user group was as simple as building a hexbeam:)

Here is the link for the site referenced in my previous posting.

http://leoshoemaker.com/hexbeambyk4kio/understanding1.html

Steve actually you said it should be resonant! Now the only way that can happen is if the reflector length is equal to the driven or has loading or something to resonate it!...MOST hex beamers have figured out this is not correct...If you model it or just put it together and start cutting this holds true..but I didn't intend to put you on the hot seat so to speak...Hey guys cut him some extra element length!!!(SLACK)...He is one of us nuts...W4HV

Something you need to consider - - When "the other guy" is using a 5
element monobander, you get the benefit of his antenna gain. When
you work someone with 100 watts and a hexbeam, or 100 watts and a
windom, then you can thank your hex, but thinking you are doing
something special working a big gun station with a hex is something
you should give more consideration to. Reports are all over the
map, and you never know the exact conditions...

OK guys just one more try, because we may have differing definitions of words like "resonant" :)

This is what I did on EZNEC, and then checked it on the REAL antenna:

1) Load the support structure with only a 20m Reflector and split it at the centre.
2) Trim its length until its impedance has ZERO reactance at 14.100 MHz (that's my definition of RESONANT; and yes, I did take account of the length of coax joining the Reflector to my analyser:))
3) Re-Join the two halves of the Reflector having noted its final length. Just to be sure, check with a dip meter that its still resonant at 14.100 MHz
4) Added a Driver cut 1.5% shorter than the Reflector length.
5) Measure the beam impedance at the centre of the Driver at intervals across the band. As predicted beam was resonant at about 14MHz (SWR=3.6 Z=14+j0), SWR was 2.3 at 14.100 and fell to low values above 14.100 MHz
5) Carry out F/B tests on EZNEC, and for real with a local Ham 2 miles away, at 50KHz steps through the band. Didn't rely on his S meter - adjusted the power at my end for the same reading his end!
6) Result - BEST F/B WAS AT 14.100 MHz

That's what I mean when I say I get best F/B at the frequency where the Reflector is resonant!

K4KIO, Leo, recently was disappointed with his on-air F/B performance and trimmed his Reflector for resonance higher up the band. Result - better F/B at the cost of some degradation in SWR.

Plenty of other folk, including Mike Traffie, say that the best F/B comes at frequencies where the SWR is deteriorating rapidly, so I think I'm in good company here!

W4HV - thanks for the appeal to treat me gently - I don't want to start the "war of independence" all over again; after all, we lost the first time :)

Clay,

You're right to add a word of caution. I guess one good test is how the Hex beam performs in a "DX Pileup" when you're competing with the "big boys" and you're all benefitting the same from the guy's equipment "at the other end".

3396. 30/40 MegaHex

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-09-23 22:07:04 UTC
From: Clay K7HC
Topic: 3396 Message: 3396

I am well on the way to constructing a 30/40 MegaHex! I have many obstacles that I must get past, but I am sure that I can complete it as planned. Whether it works or not is another question. I have uploaded some early pictures of the project to the Photo section, and will show more as I go along.

I became interested in the Hex because it is lighter, cheaper, and much smaller (turning radius) than other antennas. While it does not have super performance, it is good. When you consider that doubling your power will provide about 3 db increase in your signal, and f/b will cancel a significant amount of received QRM and QRN, it makes it VERY worthwhile!

I intend to document this project on a website (if it actually works)

Clay,
true you never know the conditions. BUT you do know yours. And you do know if you get through somewhat easily that something is working well. You also know where you are as compared to the rest of the world. And knowing how most times working against the coastlines can be very hard. Being me in Idaho working against the East coast working into Africa or Europe and having to compete against them and am able to get thru sometimes 1st or 2nd call (and sometimes 100 calls) says something I would think. I would like to use an amp with the beam to see how it works and compare it to what I have been doing since MArch. Worked several with hex beams this weekend. And they are all very happy with the beam. As am I..
Again as you say the other station with more metal in the air will always do better. I will not kid myself BUT you got to get the signal to that staion for him to hear you.. And the hex so far has done that.

Vy 73,
Ed NT4TT

Something you need to consider - - When "the other guy" is using a 5
element monobander, you get the benefit of his antenna gain. When
you work someone with 100 watts and a hexbeam, or 100 watts and a
windom, then you can thank your hex, but thinking you are doing
something special working a big gun station with a hex is something
you should give more consideration to. Reports are all over the
map, and you never know the exact conditions...

In case anyone might be interested - As shown in the pictures I uploaded under K7HC, I used 1 1/2" saddle clamps over 1 1/4" EMT to secure spreaders to the base plate. I had a difficult time locating saddle clamps, and when I did, I found a stock sell-out on these items. I bought the whole stock, so if anyone might want to acquire some 1 1/2" saddle clamps 9same as shown in the photos), I have a small stock of surplus..

3399. Height above ground

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-09-25 18:02:05 UTC
From: ae6rhxx
Topic: 3399 Message: 3399

I am considering putting up a Hex-beam, but live in a CC & R controlled community. Does anyone have any info on how low the ground the antenna can be and still get out OK? I'd really like to know where the knee of the curve is; can it be used at 10 feet above ground? I assume 40 feet would be great, but how much degradation in received/transmitted signal could I expect at 30 feet? 20 feet? 15 feet? Also, has anyone tried disguising the antenna? Some type of cover making it look like an unbrella?

3400. Re: Height above ground

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-09-27 08:34:02 UTC
From: steveeh131047
Topic: 3399 Message: 3400

Hi,

Just ran an EZNEC simulation of a 20m HexBeam at various heights which might give you some sort of "feel" for the height penalties. The model assumes that the surrounding ground is perfectly flat and has "Medium" ground conductivity and permittivity. Of course you wont have a perfectly flat ground extending to infinity (!) and so reflection and absorption from the "clutter" of other structures will likely make the performance at low heights even worse. I assumed a take-off angle of 10 degrees - typical of DX contacts. Figures are quoted relative to the performance at 40 feet:

40' 0dB
35' -1.1dB
30' -2.6dB
25' -4.1dB
20' -5.9dB
15' -7.9dB
10' -10.7dB
5' -16.2dB

There was also some degradation of F/B at the very low heights.

EZNEC isn't perfect :) but these figures should be in the right ballpark. The drop from 10' to 5' looks like a real "killer" - nearly an S point.

During testing I had my Hex at 15' and had some encouraging contacts with it. I was able to do A/B tests on 20m with a Butternut HF5B at 20ft - sometimes no difference, sometimes the Hex better, but never was the Hex worse.

Remember that a 5 band Hex is about 3' tall, so if the 20m element is at 15' the 10m element will only be at 12'

Hope this helps.

73,
Steve G3TXQ

I've seen it mounted on the ground w/o a 3' mast and it worked effectively. This would really appear to be a clothes hanger for laundry in your CC&R community.

Mine is a home-made tri-bander and the baseplate is a bit under 20' to the ground. The rotor is in a ground-mounted home-made mini-tower. I have it "tucked in" behind my garage so the top is about 2-3 feet above the garage roof line -- not really hidden (I do not have restrictions), but need to keep the neighbors (and XYL) happy.

I run 50-60W maximum and have never had difficulty even in severe DX pile-ups. I work mostly 20M -- both SSB and CW.

From: Colin
Topic: 3399 Message: 3403

I have a 5 bander up at that sort of height (~11ft to the 20m element)
and it seems to do ok.
If you inverted it (as in an umbrella) the 20m elements would be 3ft
lower and at 19ft across.. it`d also catch some serious wind once
covered in fabric or poly!

Mine is brilliant white but still quite unobtrusive considering. A
paint job to make it blend into the background would probably be a
good idea.

Looks like a good project... I will be building one which utilizes RG-58 cable (VF of 0.66) which allows the elements to be a third shorter... the only part that I'm uncertain about is to what extent the 40M elements will affect the 15m elements (first attempt will be 40-10m hexbeam, dropping 40m or 15m if the higher bands are detuned.)

The 40m element impedance will be quite low at the third harmonic (15m) and take a significant amount of power from the interconnecting feed. Of course this power will get radiated, but not necessarily in the direction you want! - I would expect gain and F/B to suffer when operating at 21 MHz.

But good luck - it sounds a very interesting project!

Hello,
I found in practice that the 40m elements are radiating quite well on 15m. This happened with all built combination from 40m single band up to the 4-bander. You will find some changes between the different 40m+ versions because the stub length is differing with every additional band while I'm feeding always from the bottom. We had this disccusion shortly with the 20m+ versions (top or bottom feeding).

We have done field measurements with a 40/30/20m version about 3 years ago. And as I remember we had a fine F/B of about 18 dB on 15m. We could not measure the maximum gain at around +/-(30-40)° like EZNEC shows. The forward signal was over the range of +/- 30° or 35° at the same level. The side suppression was much smaller compared to the bands which had own elements (40/30/20)m. If needed I can check the documentation of our field tests when I'm back home.

Results while DXing also were very promising and therfore I never added an own 15m element. I expected more problems than real advantages.

There is a file called "radiation_diagram_DL7IO-40-4.pdf" in the file section, subdirectory DL7IO.

I'm looking for feedback on installing the HX-5Bi on the same mast as a 5 element 6 meter yagi. Can this be done and if so how far apart should the two be?

I think another option could be to use the HX-5Bi on 6 meters with a tuner but I would immagine the performance would be poor.

Thanks.

When I was testing my 5el hexbeam I had it about 6ft off the ground and
made several EU contacts from Aiken,SC. It happens that the conditions
were very poor that day! Sooo if you can get the antenna as high as you
can.. The antenna from a distance is very difficult to spot.

From: nasa820
Topic: 3399 Message: 3409

What about installation above a metal roof building? Would it be considered perfect ground? Would I be measuring the height above the "ground" or above the roof? What about the effect 'near' a metal roof building?

I am looking at over 180 degrees of salt water extending out from 25,000 ft to more than 75,000 feet. I'm assuming that is perfectly level! I'm on a 'high bank' with the ground level about 80 feet above the water.

My QTH offers opportunities and challenges. The metal roof potentially offers a good ground plane for a vertical, and the salt water an ideal surface for a low takeoff angle. But, despite a lot of experimenting, I've yet to really avail myself of the potential benefits and get the "big kick" I think is hiding in this QTH.

With the hex-beam, my ideas are in the direction of a relatively low mount (say 5-10 feet) above the ground, but that would be 80+ feet above the sea. The antenna would be about 100 feet in-shore of the water line, so the question is what would have the greater influence, the ground immediately below the antenna or the sea water in front?

A lot of questions! Thanks in advance to the group.

My QTH here, bottom half of the page: http://www.rbogash.com/ham.html

The optimal height is 34 feet above ground but it works great at lower levels..mine's at about 20 ft and I can work just about anything I can hear.good luck.this is truly a great antenna almost at any height you might want to try.

I've seen it mounted on the ground w/o a 3' mast and it worked effectively. This would really appear to be a clothes hanger for laundry in your CC&R community.

Jim,

Yet another option might be to string a 6 meter element on the HX-5Bi
and feed it with a separate feedline - several folk on the Group seem
to have built succesful "6 banders".

Bob,

It depends on the "geometry" of your situation and the take-off angles you are interested in; a bit of High School trig will then give you an answer. Picture the sea and the roof as two reflectors, and work out whether the reflected wave (coming downwards from the antenna) will reach the sea, or will be reflected off the roof before it reaches the sea.

For example, say your antenna was 5' above the roof and the roof extended 30' from the base of the antenna in the direction of the sea. For take-off angles of 10 degrees or less the reflected wave will not be "shielded" by the roof and will reach the sea; so the effective height would be 80+. For take-off angles greater than 10 degrees, reflection will take place from the roof so the effective height would be 5'.

But don't forget that putting the antenna very low to the roof could result in some serious de-tuning effects. And don't forget we've only considered one direction!

Sounds like a great location though ..... any chance of a swap, Bob :)

Apologies if this is a repeat posting, the first one seems to have got lost.

3414. Re: Height above ground

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-09-30 18:46:35 UTC
From: steveeh131047
Topic: 3399 Message: 3414

Bob,

The answer to your question depends in part on how far the metal roof extends away from the base of the antenna, and on the take-off angles you're interested in. Think of the the metal roof and the sea as reflecting surfaces (mirrors). At the low angles of elevation you're probably interested in for DX (say 10 degrees or less) would the reflected wave from the antenna (10 degrees BELOW the horizontal) be reflected from the metal roof, or would it miss the edge of the roof and reach the sea. A bit of High School trigonometry should give you the answer.

If the reflected wave will miss the roof, you're in pretty good shape; if not, height above the metal roof is the important factor.

If my maths is right, at take-off angles of 10 degrees or lower, with the antenna 5ft above the roof, height above the sea is the determining height provided the roof doesn't extend more than 30 feet from the base of the antenna.

But even if the "geometry" looks like low-angle signals will miss the roof, don't set the antenna too low or you may suffer some detuning effects.

And don't forget we've only considered one direction!

Just wish I'd got that sort of location .... any chance of a swap, Bob :)

3415. 4 element hybrid 50 MHz Hex-beam

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-10-01 10:01:41 UTC
From: Giancarlo Moda
Topic: 3415 Message: 3415

Hi all,

it s shame but I still have to assemble my 5B HF
Hex-beam... I have just redone the roof of my house
and I have no antennas...so maybe I will be forced to
assemble the X-beam.

I am also interested on 50MHz and I have an idea that
maybe dodgy or maybe it may works.....

I was thinking about a 4 element hybrid Hex beam, with
two center classic Hex elements and two additional
linear element maybe folded at the end.

One of the X element will be the radiator, the other
one the first director and the other two will be the
reflector and the second director.

This idea is also due to the fact I have not enough
space over my roof and cannot invade the neighbours.

In this group there are clever members than can
simulate such solution and see if worthed or not.

If it is not clear what I mean I can sketch a drawing.

Thanks and best 73

Gian

Clay's got a real interesting project here.

Perhaps I should explain one aspect of the dimensions on Clay's WebSite before anyone "blindly" copies them. We deliberately cut the Driver shorter than normal (430") so that it will present a large capacitive reactance which can then be matched with a parallel inductor. This technique (the classic "hairpin" or "beta match") produces a very low SWR at the design frequency - much better than the 2:1 or 3:1 you get on a conventional design at the frequency of max F/B. But YOU CANNOT USE THIS APROACH ON A SINGLE-FEED MULTI-BAND HexBeam.

Clay is planning to run separate feeds to his 40m and 30m elements, so has the freedom to do some "monoband matching".

Topic: 3418 Message: 3418

Hey look!

If you haven't seen it yet go to
http://www.arraysolutions.com/Products/optibeammain.htm
and look at the new OBW10-5 Optibeam. This is a 30 lb. 10 element 5
band mixture of Moxon rectangles and other more Yagi-ish type
elements. The problem with a Moxon has been that one cannot "nest"
elements to make a multi-band unit as you can with the Hexbeam. This
new antenna uses full length elements and has a three dimensional
structure like the Hexbeam. As a Moxon is a member of the X-beam, Hex-
beam and other close spaced, end coupled family of antennas the specs
are similar and plots for SWR, gain, f/b, and patterns are given.
I have no connection with Optibeam or Array Solutions but I assume
other of the group are interested in all small sized
beam antennas. I would sure like to hear about how it performs.

Allan,

Thanks for drawing our attention to this. Like you say, folk have had trouble nesting the Moxon Rectangle. It's interesting that this design, and the Optibeam OB8-4M, fly in the face of Cebik's advice not to try to nest Moxons for "adjacent" bands. I don't know whether the problems have been maintaining the impedance match, or maintaining the antenna patterns.

Just one point - I don't think this is a three-dimensional array. If you look carefully at the photo you'll see that what looks like a sloping wire element is actually part of the support structure - all of the elements are actually in a single horizontal plane. I wonder if anyone has ever tried nesting Moxons with vertical separation as we have on the HexBeam?

There seems to be enough info in the .pdf file to produce an EZNEC model of the array - I'd be interested to see how it performs across the full bandwidth rather than just at one spot freq!

It's an interesting design - but significantly bigger than an equivalent Hex, and for my money not as elegant looking :)

Hi Steve,
The three dimensional part of the antenna is mostly support
wire/cords for the elements. Since Moxon rectangle antennas
are used, then it has to have about 25-26 feet wingspan and have
greater turning radius.
As a matter of curiosity I looked at the web site of the MaxiMoxon
(a series of single band Moxons introduced about a year ago) and
found that it no longer existed. Their antennas looked well built
and not too expensive. Speaking of cost the OBW10-5 sells for
$1095.00 in the USA (there is a note of a 16% tax in Europe).
Time will tell.

Unless my math fails me, the OB8-4M has a turning RADIUS of just
over 28'. That's a larger arc than my MegaHex (30/40 meter) which
is UNDER 20' turning radius.

Well, my math failed me!! The turning radius of the OBW10-5 will be about 14.3 feet - sorry!

Greetings all,

I want to install a 3 element 6 meter beam about 6 feet under a Hexbeam. Anyone have any experience with this installation? Would there be any degradation in performance with either beam?

Thanks in advance.

3425. Length of Spreader

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-10-08 04:43:52 UTC
From: slolawfirm
Topic: 3425 Message: 3425

Hi Folks,

My hex beam is at the assembly point... on question though, based on an Excel spreadsheet posting, a calculation of the length of the spreaders is provided.. However, no info is given as whether this is linear (unflexed) or bowed (flexed) nor an info on where the measurements are being attained from. I still would like to try integrating a shortened 40m element, but need some guidance as to whether the calculated 12' is linear or after the spreader is bowed.

An info would be helpful (I am assuming that the arc isn't very important so long as the correct element lengths are maintained.)

Regards,

Phil KM6CZ

Topic: 3425 Message: 3426

Phil,

Here's some typical 40m dimensions for 16 guauge wire which might help you:

Reflector 1/2 length = 446"
Reflector end insulator = 8.6"
Driver 1/2 length = 437"
Driver end insulator = 13.4"

Distance from Centre post to Driver-spreader support point = 225"
Distance from Centre post to Reflector-spreader support point = 227"
Distance from centre post to end insulators = 228"

So the "worst case" is that you need at least 228" between the terminals on your Centre Post and the tip of the spreaders to fit this beam in. These dimensions are "STRAIGHT LINE" measurements, not distances measured following the bow of the spreaders. How much longer the spreaders will need to be depends on how much they bow, and on how they are attached at the base plate [in a design like Leo's (K4KIO) you gain a bit because the spreaders start at the outer edge of the baseplate]

Hope this helps. Good luck!

Just bought the 20M light-weight version. Took me only about two hours to assemble the whole thing (including reading the directions) and to mount it on a 10-ft pole stuck in a trash can sitting on the patio.

What is unique in my situation is that I did the whole thing BY MYSELF WHILE IN A WHEELCHAIR! I was amazed that it was so easy. With the post in supported in a trash can, I was able to rotate each of the elements to where I was sitting in the wheelchair and make all the connections. Everything went together exactly as described, no parts missing, nothing that didnt quite match up, no holes misaligned, no problems whatsoever.

Even tho it is now only 10 ft off the ground (some friends are coming tomorrow to hoist it to a 30-ft mast), I have been getting reports 2-3 S units over my G5RV. Now I kinda wish I had gotten the 5-band version!

From: slolawfirm
Topic: 3425 Message: 3429

Thanks Steve,

The arrangement I'm using incorporates shortened 40m elements (i.e., RG-58U cable.) The basic structure has been finished and the Maxgain fiberglass rods are holding the weight of the cable fine.

The only question that comes to mind is how much vertical spatial difference is required between the elements of different bands.

At this juncture, I could easily leave all the elements in approximately the same horizontal plane, but suspect that this would not work due to element interactions. (although this is essentially becomes a sort of yagi.

Another alternative, is to use the support cables (kevlar/dacron mix) for attaching the problematic elements to the antenna structure.

There was another antenna called the Cobbwebb (folded dipoles) which did just this and it worked fine; although the antenna itself did not perform well at all.

The engineering challenges is what makes this antenna fun to construct.

Regards,

Phil KM6CZ

Phil,

I'll be interested to hear how you get on with the coax elements - it's always seemed to me like one of those "too good to be true" ideas. I'm sure the resonant lengths will decrease by the velocity factor, but I'm particularly interested to know if there are significant losses in the coax elements.

Be sure to get those coax Reflectors resonant at the required frequency by measurement rather than prediction - I doubt you'll be able to rely on the velocity factor being accurate.

With regard to spacing, I don't think there are any hard and fast rules. Most folk seem to end up with vertical spacings dictated by the "bow" in their spreaders. As you say, it seems likely that interactions will be greater if all bands are in one plane, so I think I would play safe and stick to the "typical" spacings. Leo and Holger's Websites quote very similar numbers so I would go with one of these (scaled for 40m if necessary)

I sometimes wonder if part of the problem nesting multiband Moxon Rectangles is because folk don't go for vertical spacing!

I know the CobWeb antenna well. I've built a couple of HomeBrew ones. It seemed to me to perform exactly as you would expect a "bent" dipole to - i.e. no Magic :)

Hi All
Great to see new ideas being explored.

I would think that logically the physical spacing only needs to be sufficient to reduce interactions.

Having said that.. I wonder if, in the case of a single feed multiband hexbeam, the actual required spacing is more to do with the feeding arrangement lengths than with prevention of element to element interaction?

With seperate feedlines for each band you may have more scope for playing with the vertical spacing.

While on the subject of using seperate feeds for each band..
would the feedline be best left open circuit (at presumably a mast mounted switchbox) on unused bands or perhaps grounded?
and indeed would the open or shorted unused feeds then affect the performance?
It seems likely they could act as stubs to lengthen/shorten the unused driven elements with some potentially bad results.

Seems there`s always another question to ask hi

Colin,

You raise some interesting points. Here are my thoughts ... not yet backed up by any modelling!

>
> Having said that.. I wonder if, in the case of a single feed
> multiband hexbeam, the actual required spacing is more to do with
the
> feeding arrangement lengths than with prevention of element to
> element interaction?

I doubt it. In my experience the impedance transformations introduced by the interconnecting feedline have represented a PROBLEM to be overcome rather than something that can easily be exploited. Of course one arrangement (seen on a website) which provides the best of both worlds is to use the conventional support structure but slope all the Drivers back to one common pair of terminals at the Centre Post, neatly doing away with the interconnect problem.

Yes, you can envisage certain feeder lengths that would bring an "unused" Driver to resonance and cause some funny effects. Without knowing the feeder length you can't say whether O/C or S/C would be better ..... so why not play safe and switch in a terminating 50 Ohm resistor at the switchbox - this would always result in 50 Ohms across the unused Driver whatever the feeder length and prevent it becoming resonant out of band :)

Ok,

I'll post some results when I've completed the antenna.. I used the same batch of coax to build the hybrid hex and it worked fine (although the bamboo support did not last long.) Even with the shortened 40m elements, the antenna is approx 25' in diameter.

I plan on tying all of the driven elements together at a common feedpoint (AKA cobbwebb antenna.) The common feedpoint will attach to a 1:1 current balun. If this doesn't work, I'll switch to no.6 gauge copper wire arranged more like the traditional hex feedlines (I want to keep the balun to ensure optimum F/B and gain.) One thought I had was to replicate Moseley's balanced matching feed used on their 5 band beam antennas (gradually narrowing parallel lines.)

In any case, thanks for the interest and stay tuned!

Regards,

Phil
KM6CZ

Hi Steve
Thanks for your informative reply.
I guess there are hurdles to overcome no matter which way you go.

After looking at Doug`s (VE3EFC) novel method of sloping the elements.
It occurred to me that if all the elements started at the top of the post, the wires would also act as supports for a horizontal spreader instead of a curved one..pretty much like a suspension bridge or the boom stay on a long yagi.

I did a quick model of a 20m monobander with just the post to knee wire portions sloping down with the outer wires flat as normal and the performance seemed to be largely unaffected.
A 5 bander with all the element outers "in plane" may well cause some headaches though.

I did notice the gain and f/b curves peak at about the same freq but that could be the result of a modelling error on my part.. i`m no expert.

I`ve plenty of fibreglass so i may give the design a go just to see how well it fares against the standard configuration.

From: Steve
Topic: 3435 Message: 3435

Hi Folks,

When I first got interested in the HexBeam, I wondered if there might be other element "shapes" that could form the basis of a compact beam. So I modelled about a dozen different Driver shapes, looking at their 20m Gain, resonant Impedance, and SWR bandwidth. The "Holy Grail" was a shape with a very small turning radius that had high performance parameters - I didn't find it, or I'd be off making my millions :)

I thought some members of the Group might be interested in the results, which are now in an MSWord document within the G3TXQ folder of the Files section. Hopefully the description of the different shapes will be self-explanatory. Some of the shapes have a vertical component - for example, the quad loop - so although the turning radius is quite small you have to rememebr that it also occupies vertical space.

I guess the clear message from these results is that you never get "something for nothing" - generally, the bigger the turning radius the higher the Gain, Impedance and SWR. There's quite a lot of scatter, but in the case of Impedance there's almost a linear relationship with turning radius.

As you'd expect, the performance of our favourite antenna (the Hex) is pretty much consistent with its size. Perhaps the most impressive is the 14.6' dipole loaded with eight 2'spokes at each end - of course the problems come when you try to turn this into a multiband beam!

73,
Steve

Colin,

Well done - we learn a bit more with every posting!

I've just tried two quick separate configuration changes on my 4 band (20-17-15-10m) EZNEC model:

1) I sloped the 20m, 15m and 10m drivers to a common feedpoint at the 17m position. I kept the Reflectors in their normal horizontal positions.

2) I reduced the band spacing to 1/2" to simulate everything being in one horizontal plane! You could enviage this being built with "flat ribbon" cable going out from the centre-post and "peeling off" the various band elements at the appropriate point on the spreader.

In both cases the basic antenna performance (particularly F/B) was affected for the worse. Option 2 was particularly bad. I haven't had a chance to look in detail why this is happening, but a quick look at the EZNEC current distributions shows that the "unused" band elements are being excited significantly more than on the Classic model. Perhaps we shouldn't be surprised that bringing the "maximum current" sections of the Drivers so close together has this effect.

Feedpoint impedances change with the various options, but in neither case did they look to be particularly better than the SWRs on the Classic model. So my earlier thoughts that sloping the Drivers to a common feedpoint might simplify the matching looks to be wrong :(

3437. New File - Improved HexBeam performance?

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-10-11 14:42:11 UTC
From: Steve
Topic: 3437 Message: 3437

Hi Folks,

When I first joined the Group I posted an EZNEC model of a HexBeam with an alternative feed arrangement which seemed to promise improved performance. I realised recently that I had never posted the corresponding performance graph!

It can now be found in an MSWord file called "2 Driven performance graphs" in the G3TXQ folder of the Files section.

Take a look and you will see that the alternative feed arrangement promises significantly better and "flatter" performance across the band; only its Gain at the bottom end of the band is inferior to the Classic feed arrangement. And what is this alternative feed ? ..... Simply connecting the Right side of the Reflector to the Left side of the Driver and vice-versa - making it a Driven array rather than a Parasitic array.

Just a couple of cautionary words before you all go off and re-wire your HexBeams :)

1) I've not yet had a chance to try this "for real" - so far its just been a modelling exercise.

2) The feedpoint impedance tumbles when you feed both Driver and Reflector (a characteristic of most Driven arrays) - so the model includes a transmission line matching section. This is fine for a "monobander" but I've not yet had a chance to figure out how a "Multibander" might be matched.

I hope soon to build a 10m monobander to try out the idea - but if someone wants to have a go in the meantime, please do and let us all know the outcome.

73,
Steve G3TXQ

Steve,

Have you read the paper on supergain? It is in the files section
under Publications.

Topic: 3418 Message: 3442

The discussion of the Optibeam prompted me to wonder how its performance compares with the Hexbeam and so I took Cebik's modeled data for the Mox and the Hex and put them on the same graph. You can see it in the attached Word document.

Clearly, the Mox mono band outperforms the Hex monoband based on these data but the physical configuration of the Hexbeam, certainly in a multiband arrangement, seems far superior in my view.

Comments are welcomed.

73,

Leo, K4KIO

Steve <steve@...> wrote: Allan,

Thanks for drawing our attention to this. Like you say, folk have had trouble nesting the Moxon Rectangle. It's interesting that this design, and the Optibeam OB8-4M, fly in the face of Cebik's advice not to try to nest Moxons for "adjacent" bands. I don't know whether the problems have been maintaining the impedance match, or maintaining the antenna patterns.

Just one point - I don't think this is a three-dimensional array. If you look carefully at the photo you'll see that what looks like a sloping wire element is actually part of the support structure - all of the elements are actually in a single horizontal plane. I wonder if anyone has ever tried nesting Moxons with vertical separation as we have on the HexBeam?

There seems to be enough info in the .pdf file to produce an EZNEC model of the array - I'd be interested to see how it performs across the full bandwidth rather than just at one spot freq!

It's an interesting design - but significantly bigger than an equivalent Hex, and for my money not as elegant looking :)

No go at this ad it looks and is to big and to complicated to travel with it may have little more gain than a HEXBEAM but i belief not as easy as a Taffy factory hex beam to assemble and get up my one has fallen over a few times in the erecting and had no damage done and it has done some traveling all ready , nice to read about all of this but do believe Hex beam is No 1 , 73 de ZL1PDT

Subject: [hex-beam] New Antenna from Array Solutions OBW10-5

Hey look!

If you haven't seen it yet go to
http://www.arraysolutions.com/Products/optibeammain.htm
and look at the new OBW10-5 Optibeam. This is a 30 lb. 10 element 5
band mixture of Moxon rectangles and other more Yagi-ish type
elements. The problem with a Moxon has been that one cannot "nest"
elements to make a multi-band unit as you can with the Hexbeam. This
new antenna uses full length elements and has a three dimensional
structure like the Hexbeam. As a Moxon is a member of the X-beam, Hex-
beam and other close spaced, end coupled family of antennas the specs
are similar and plots for SWR, gain, f/b, and patterns are given.
I have no connection with Optibeam or Array Solutions but I assume
other of the group are interested in all small sized
beam antennas. I would sure like to hear about how it performs.

Mike,

I'm still confused :)

Do we have a 28 meter band ? I'm guessing you meant 20, 17, 15 and 10 meters, but I may be wrong.

Barry,

Thanks for pointing me in the direction of this paper. I "skim read" it when I first joined the Group but, encouraged by your posting, I've just had a more-thorough read. It's very interesting stuff.

I guess this comment from the Conclusion section of the paper says it all:

"The dream of a small, high gain and highly directive beam remains Pie in the Sky"

I'm reminded of the years I spent early in my professional career searching for error control coding techniques that would meet Shannon's Limit. If you recall, Shannon's Theorem states that if a communications channel has a certain Signal/Noise ratio it must be possible to signal through it at zero error rate if you keep the bit rate below a certain threshold.

Unfortunately it's an "Existence Theorem". In other words, it says that a way of doing it must exist, but it doesn't tell you how to do it! Modern coding techniques get close to the Shannon Limit but no-one has yet achieved it.

Some of the SuperGain predictions seem to be in the same category - theoretically possible, but not achievable within our present state of knowledge.

Perhaps when we Hams have room-temperature superconductors with which to construct our beams it'll be different ..... :)

From: w2bxr
Topic: 3449 Message: 3449

I also experienced problems with a "cutting board" material used for making a base plate. It was almost 1/2" thick and some type of white plastic. The beam was still about ground level in the tuning/building stage for about 4 days. I noticed the warping soon after I assembled it and several cracks in 4-5 days. Obviously I am going to remake the base out of some UV resistant material or aluminum.

Did make some nice contacts on 20 and 17, which is all that it was buit for, even though the elements were about 4 ft off the ground. Good learning experience for the final build.

Gene, W2BXR

I used a thick cutting-board (from Tesco for UK readers), and so far have not seen any problems. But I bolted 6 lengths of stiff aluminium angle to the board, and then tie-wrapped the spreader to the aluminium. It seems to me this might unwittingly have resulted in a useful stiffening of the baseplate.

It would be interesting to hear what spreader-mounting method was being used by the folks that have suffered failures, just to see if there is some common factor in play.

The Florida heat and UV probably caused the failure. Did you use a double thickness boards?

Harold,

80 degrees is typical at the operating frequency where F/B is
highest, but where the gain is about 1dB below max.

If you were to operate at the frequency where gain is maximum, the
beamwidth would be a little less: 72 degrees - however the F/B would
be a dismal 6dB!

So your 60 degrees is not so far off the mark!

Topic: 3455 Message: 3462

Thanks, Steve. I had never really put any intensive study into it (being a relatively new and ignorant Ham despite my considerable age). The other homebrew Hexbeamer here in town had had a bit of trouble with imprecision in his rotor. I had guessed that the beamwidth was wide enough that as much as 10 or 15 degress off would not cause him much problem. I don't really think his light rotor was that far off and your beanwidth figures will allow me to reassure him.

Hello,
Spoke with Mike yesterday and a mutlibander is heading my way.

Two questions:
What is the minimum length of mast to have above the rotor for this beam?
What size drill bit do I need to drill the hole for fixing the beam to the mast? Seems like whatever size I need it is always dull. Want to have a new one here when the package arrives.

Andy,
When I was speaking with Kathy (sp?) this weekend she said
they do not use email.
My quess is Mike is quite busy as he has his hands full with the Hex
Beam business and taking those related calls.

I am afraid he still is. I am not sure if he is affected, but in
remote areas in US, they only have very unstable dial-up connection.

From: slolawfirm
Topic: 3435 Message: 3469

Hi Steve,

I should be assembling the shortened 40m - 10m hexbeam this weekend; (took some time to get the flexweave wire for the 10 - 20m elements.) The 40m elements have already been made. (The weight of the RG-58 may be a factor.

One thought though, if connecting the reflector and driven elements seems to improve performance, would feeding the multiband as if it were a log periodic work? (I am not versed in modeling, but will give it a firt shot; I suspect the feed point impedence would be increased requiring a 4:1 balun.)

Thanks,

Phil KM6CZ

Phil,

I would "play safe" and stick to the conventional feed arrangement for now. My idea is as yet totally unproven, and your design has enough original features without the addition of another "unknown"!

I'll give your Log Periodic idea some thought. If I understand it correctly, in a LP you are driving all elements simultaneously and relying on the fact that only the 2 or 3 that are close to resonance will respond; these then form a 2/3 element array because of their relative lengths.

My feed arrangement is more akin to the W8JK type of array, in common with which it exhibits a very low feed impedance - of the order of 8 Ohms. It also requires a quite different Driver / Reflector ratio than normal in order to get the right relative current magnitude and phase for beam action. It may be in practice that the high circulating currents produce losses which nullify much of the improvement!

I'm currently modelling folding the elements - this shows some promise, not only for my new feed arrangement, but also for the conventional feed. It improves the bandwidth and seems to produce better average gain figures.

3471. Stray RF

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-10-20 04:57:42 UTC
From: kc0rdg
Topic: 3471 Message: 3471

All,

I have purchased the Hex 5 bander, serial 449. So far I am loving it, however just having upgraded to General this week, I am not sure what I have been missing as the previous antenna was a Inverted L used just for listening as a Tech. That said, I am having some issues with stray RF and need some help.

The Hex is mounted to my chimney the 20 meter element being at about 30 feet. It's fed with a 60 foot run from feedpoint to rig with LMR-400 Ultra. Below the Hex elements I have installed 6 type 77 torroids that I ordered with my Hex. The station/shack is about 3-4 feet underground in my basement and the feedline runs up and out the window, next to the house and up to the Hex.

None of my station equipement is grounded, I was under the impression that I did not need a ground with this setup, apparently I was wrong :)

On the same side of the house where the feedline exits, there is a sidewalk that runs along the side of the house which prevents me from driving a ground rod right outside the window. I have made a 6 inch copper pipe 'rod' and used copper flashing to tie my radio and tuner to it (with seperate runs each). There is then a seperate from it run out the window, across the sidewalk and into a copper pipe that I hammered into the ground. When I TX my speakers will have some fuzz or buzz to them sometimes. It mostly happens when the beam is pointed in the direction of the computer/shack (incidentally this is the Europe path). If I point it towards the Caribbean or Pacific, it mostly goes away. If I put my hand to the radio and touch it or the tuner, it completely goes away. It seems to happen on 20 meters, but oddly enough only sometimes. 17 meters it has happened but only once. On 15 meters, my computer mouse stops working! Another thing is, I cannot tune the antenna on 30 or 40 even though I know it is possible with my tuner (AT-100Pro) and that the Hex has the ability to be tuned on these bands. When I try it, the tuner goes nuts, then quits and the rig shows minimal power out and huge SWR if I TX.

All of this has led me to believe I have a stray RF problem. The question is, what is causing it and how do I get rid of it once and for all?

Someone mentioned it might be because my run is 60 feet and that is a 1/4 wave on 20 meters. Someone said to install a choke balun, however I have 6 torroids on the line already. Someone said to ground all my stuff, which I have to the best of my ability with the location of the shack. I have pictures up on my site, the direct link to my antenna

page is http://www.qsl.net/kc0rdg/Hex.html

HELP and THANKS!!

Elijah/KC0RDG

Elijah,

Sorry to hear of your problems.

The suggestion that you add more toroids is valid; just because you already have some near the beam doesn't preclude the need for some elsewhere on the coax run. It's worth trying a few more at the shack end.

I'm sure you'll get lots more good advice!

From: Mike Van Winkle
Topic: 3471 Message: 3473

There are three things to note on your installation
that have a potential to create problems. First a lack
of an rf station ground ....NOT AN ELECTRICAL
GROUND...you seen to have solved the electrical part,
at least for your radio. Did you also ground the
computer chassis? I know many will debate the need for
RF ground but it does make a huge difference,
Secondly I also notice the distance the antenna is
above your station, It is close to 1/4 wave on 20.
This presents a high level rf field at your station
particularly on 20. Thirdly the coax length is
approximately 1/2 wavelength distance on 20 went you
account for the velocity factor of the coax....
There might be a simple fix for part of the problem!
Add about 40 feet of coax to your install and this
should get your tuner out of the mud. Then install
some 1/4 wave bare wires buried just under the sod
connenected to you ground pipe for the main bands you
will use..This creates an RF ground..AND BE SURE YOU
GROUND THE COMPUTER>>>THEY USUALLY HAVE LITTLE
GROUNDING!....W4HV

No it is not grounded, I will ground the computer. I was wondering if this might have something to do with it.

> Add about 40 feet of coax to your install and this
> should get your tuner out of the mud.

40 feet!? Could I get by with say just 10 feet?

> Then install
> some 1/4 wave bare wires buried just under the sod

This is one reason I bought the Hexbeam and stayed away from the Inverted L, it was fed against ground and required a extensive radial system. I do not have the yard to put many radials down.

I was wondering if I just put a line isolator from Radio Works on, make a choke balun and put the 6 torroids on, would this do it? Rather than make an extensive RF ground, I'd just like to the choke the hell out of it before it even gets to me. Is this a possibility?

okay on not grounded...i must have
misunderstood...Regarding grounds of an rf nature, it
is not always about something to "work against" as in
your L set-up. This time its more about dissapating rf
energy being picked up by wiring and by your antenna
feedline. They don't have to be straight or even
perfect in length!...Just put in what you can and it
MAY help!..Surpringly it usually helps your recieve a
bit also!
On the feedline length, 10 feet will change it some
and may be helpful, but you really need the longer
length to allow you to get away from that 1/2 wave
multiple.Just roll the extra line up loosely into a
coil and put it out of the way...also honestly I
noticed you ae using a tuner they need that length of
coax to prevent problems with standing wave high
points along the line which can cause some very
strange results when you try to tune..THAT TUNER NEEDS
A GOOD GROUND TO GET BEST RESULTS!!!!!!! Also be sure
that hex-beam is presnting a reasonable SWR WITHOUT
the tuner...Traffie builts a good product but it
doesn't hurt to check!...W4HV

On this note, is it possible to totally dissapate the RF without the need for radials? Would it hurt to have a RF choke/isolator near the radio in the shack? Forgive me, I am new to all of this and can only learn by asking! :)

The Hex does have great SWR without the tuner inline. Incidentally, I took it out because I am unable to use it anyway as it just tries to tune like crazy, can't find a match and stops.

I guess another question I have is, I can get 40 feet of coax and coil it up in a corner somewhere, however this will a) cost money and b) put my total feedline at 100 feet. Is 100 feet a half wave of something?! Or put another way, could I do say 20 feet instead of 40 brining the total feedline to 60 feet? What it boils down to is, what is the least amount of cable I would have to buy to not have a multiple of 10-40m? Also, putting a "bullet" in and attaching more feedline will add some loss to the line. Something I wish I would have known before I did the whole project! Maybe it will be negligable.

The main issue is, I live in Minnesota and it is getting colder out and I'd like to resolve this issue before it snows here. Thanks for your help and if anyone else wants to chime in, feel free.

Thanks for the help,
Elijah

I use a 100 feet of RG8/u

Mine has flat swr (1.1 to 1.2) on all bands except 15, and 10 meters. There it will touch 1.3 or so. I do use a tuner . But I doubt it makes much difference in signal strength.
No RF into the shack. But with out good grounding anything is possible.

Elijah,

There are no "right and wrong" answers for these problems - everyone's situation is different.

I would try ferrite beads near the rig as a first step - it's relatively low cost and its probably the easiest solution to implement. If it doesn't work, move on and try some of the other suggestions.

By the way, leave your ferrite choke that is close to the antenna in place; as I said in an earlier posting the choke near the antenna doesn't rule out the need for one near the rig (and vice versa).

Good luck,
Steve G3TXQ

Elijah,
I think there is a bit of confusion with the length of the feedline. First the HexBeam is approximately 1/4 wave (20 meters) higher than your shack. The 60 feed line is electrically 90 feet long (divide the physical length by the velocity factor) which is 1.3 wavelengths. So the notion of adding 40 feet (for a round 100 feet) would give 2.2 wavelengths. I think the 100 foot (physical length)came about because someone bought 100 feet of coax and didn't want to cut it up. The problem is with the shield of the coax which isn't effected by the velocity factor of the cable. What you want to do is put impedance in the shield path which is best done with ferrite cores.
Sometimes adding extra length to the feedline will make matching to the antenna a lot easier. This often requires a few extra feet of line. There is nothing magical about exactly 100 feet of coax.

In reguards to the radials, do they have to be buried? Do they have to be bare copper wire touching the soil or can they be insulated just laying on the grass?

I was able to find a 15 foot piece of coax I had laying around. I added that to the 60 foot and added a choke balun, 8 turns around a 2 liter pop bottle. The tuner now tunes on 30 and 40! So I am starting to get there.

Bare wire is best..It is usually easy to just split
the sod and push them under...I use an old ax or a
flat shovel to split the sod...Just push the wire in
and step on the sod ...when you get done water the
grass and in a couple weeks you would never
know.....Just laying on the grass will help but not
the best situation.People step on them! Get tripped,
Sue Ham op...NOT GOOD!!That set-up works single
purpose rf ground..Bare buried also helps electrically
as well!>>>>> Good luck! Sounds like you are on your
way!!!W4HV

Congratulations Elijah on your new Hex-Beam. Am sure you will get many years of enjoyment from it. I noticed that you have received a lot of advise about solving your installation problems, which is a wonderful part of this Group.

I would like to note that when you have a proper installation, the length of the feed line is not really material, i.e., the SWR is a constant at all points along it. If it isn't done correctly, then it will vary and fiddling with the coax length will give some apparent relief, but the problem is just hidding. ;-)

One thing I don't believe anyone has mentioned is to check your coax connection to the connectors. I have seen too many cases of improper installation of the PL-239 causing such a problem. If you are unsure of the quality of the connection, cut off the old ones and install good quality ones properly. This is also a good time to add more Amidon FB-77-1024 beads. Put 10-12 if you really want to be sure. I use 8 myself, but a few folks needed more. You can also put some on the transmitter end as has already been suggested. Don't wrap your rotor cable with your coax.

If you have a RF current meter like the MFJ-853, then you can observe what current is on your coax shield exterior when your transmit.

You really don't need a ground with this arangement other than for safety issues. I have set up a Hex-Beam portable many times at 30-50' with a rotor and enough coax to get to the camper or whatever. The power generator was isolated from the radio by an UPS. No RFI issues at all. And yes, I was using a computer in general ... Field Day in some cases.

There was a case some years ago where a fellow was close under his HB (6-8') on the 2nd story of his house and he had RF problems. He had a ground wire tie wrapped to his coax for a good distance and this then when to a ground rod outside. He had to separate the ground wire and coax, and put an atrifical RF ground (MFJ-931 for example) in the ground wire (by the radio of course). As someone mentioned, the electrical ground isn't the same as an RF ground. He got his station operating FB after a bit of work.

Regarding the coax Elijah, I suggest you check any other jumpers you have in your system, even if you think they have been FB in the past. They can also cause a problem.

Just think Elijah, getting your installation working is often far easier than solving the problems associated with getting a mobile

rig operational! :-)

Topic: 3483 Message: 3483

Hi all

I live in a small seaside lot, terraced with small garden. I am fortunate to have great neighbours and am looking to out perform my MQ1 Mini Beam.

I have a 41 foot two section tower, with an old Kenpro rotator. I have 4 5 metre fibreglass *crappie* poles at my disposal, and am able to get my hands on two more fairly rapidly.

Is there any interaction from a conductive (aluminium) centre plate, and I take it (duh) that the angles between poles is 60 degrees?

I am looking to build a (possibly) 4 band antenna, 20/15/17/10, do my basic outlines sound feasible?

I have seen the 40 metre versions in the pictures on the group, and they look just a little too big for my modest qth.

I would however LOVE to be able to build onto my frame a 30 metre beam if I had enough spreader.

Looking forward to any replies, and thanks for your patience.

Hi all,

At w/e I was operating portable on Norfolk coast and in the search for batteries to be able to operate the following day wandered into a fishing / angling shop and found 4m and 5m versions of the 8m and 9m telescoping poles I use for portable operation. The costs were £5 for 4m and £8 for 5m which seemed OK. I have a project that needs a couple at home anyway for a 4m 2 el beam so I bought 2 or each. However I remembered the hex beam and thought as I had never seen these on sale anywhere before so asking the group is £5 for a 4m pole about right?

No shipping costs etc and I could ask a relative to buy 6 for a hex beam that could be an xmas week project.

Dom,

Yes, £5 is about right for the 4m ones. I bought 8 on-line from
www.MOEFish.co.uk and paid £43.91 total including £3.99 postage.

Part number from MOEFish is: 73014 Shakespeare - Spear-Lite 4m Tele
Pole

They've got just a nice amount of "bend"

Get building - you wont be disappointed!

Kev,

There are no "dumb" questions in this game - we're all learning :)

Yes, the angle is 60 degrees. Dead easy to construct with a pair of compasses if you remember your maths!

Lots of folk use an aluminium baseplate (NOT centre pole), as does the commercial one from Mike Traffie, so you shouldn't have any problems.

Take a look at Leo's well-illustrated construction site if you want more detail: http://www.leoshoemaker.com/hexbeambyk4kio/general.html

73,
Steve G3TXQ

Hi Kev
You might also try Chris at F.T.D (Fishing Tackle Direct)on Ebay
I bought 7x 8m and 8x 5m and it cost £56 incl the postage.

The reason for the low price is they can`t be sold for angling.. eg:
broken top eyelets, cracked plastic buttcap or simply a torn plastic
bag. None of which precludes their use for hexbeam building.

Most are still in the shed as i used heavy duty fibreglass tube from
RBJ Plastics for my 5 bander (2years old and going strong)
but the rods are there pending further antenna experiments ;)

Colin

I just took a look at RBJ Plastics website - interesting stuff.

If you've already answered this question just point me in the right direction; otherwise .....

I wonder what tubing combinations you used on your 5 bander - ODs, IDs, lengths etc. And did you get the same sort of "band spacings" as folk get with the "crappie" poles - in other words did the fibreglass tube take up the same shape?

Hi Steve
I used 19mm dia (3.2mm wall) and 12mm dia (2.25mm wall)which worked fine, it does tend to "bounce" a bit on really windy days.
It`s been up about 2 years and overall it`s good as the day it went up.
The spacing was a bit adrift but only between the plate and the 10m element ..maybe 8" instead of 10" as the heavy wall (1/8") didn`t bend enough in the short distance from the plate.

It`s virtually indestructable compared to fishing rods and you can be very brutal with it without worrying too much (i haven`t managed to break any yet!)

If i were to build another i`d go for a slightly thinner wall as the heavy stuff is overkill, something like this perhaps:

3 off 20.6mm OD x 16.2mm ID x 5 metres
3 off 16.2mm OD x 12.2mm ID x 5 metres
which may come to around £132.36 incl the vat and delivery..full 5.1m lengths.. not cut into pieces :)

Mine arrived within 24hours ..140miles via overnight train and lorry.

If you add 3 lengths of 12mm x 2.25mm wall (not too pricey from what i remember) you could share the expense with a friend and build two complete hexbeams with 3 section spreaders.

The wind took my 80m inverted L down today.. but the hex is still up

NO !!!!!!It can be any material strong enough to work with structurally!!! It needs to be able to stand UV rays, heat, cold, water, snow, and ice...You guess why traffie picks metal...Fit all these condition and lasts moe than a few years...Marine plywood painted with poly or spar varnish works well but you may want to make it a bit larger than the meteal version...One guy here used a plastic cutting board and it worked for him! Another tried the same and the florida sun made short work of it. Use your best choice of material and have fun playing with it!....W4HV

I`ll agree that almost anything can used if it`s tough enough but for
a trouble free once only job.. 1/4" (6mm) aluminium plate is probably
the best way to go.
NS4 grade aluminium is good as it`s suitable for use in marine
environments.

Tip: Try to persuade the wife to drop into a small engineering firm
to buy a 12" x 12" x 1/4" plate.
Being female they seem to get the most amazing discount..especially
if it`s for a "school" project :)

3494. Benefits by increasing end spacing

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-10-30 09:15:42 UTC
From: Steve
Topic: 3494 Message: 3494

Hi Folks,

Encouraged by some earlier work by Leo (K4KIO) I have been running EZNEC simulations - 150 at the last count - of a 20m Hex at various end spacings. In a nutshell, increasing the end spacing .....

1) .... improves the peak F/B performance very significantly, although the bandwidth over which the F/B exceeds 10dB remains unchanged

2) .... modestly improves the forward Gain

3) .... increases (worsens) the 50 Ohm SWR performance

Interestingly, the F/B performance reaches a maximum with endspacings 80% greater than the values we have typically been using. The same trends were observed at 10m with a maximum at +60%.

I have published the detailed results in the Files section for those who would like to know more. Look for the MS Word document "End spacing experiments" in the G3TXQ folder.

Hello.
I tried to download "model-2017151210.zip (2kB)" from the site of DL7IO but link do not work.
Anyone know were I can found a 20/17/15/12/10 model (eznec, 4nec2 or mma) with TOP feeding ?
I have done a 4nec2 model but with bad result

Thanks in advance, Giorgio iv3ddm

Giorgio,

I have uploaded a 5 band Top Feed EZNEC model to the Files section of this Group. Look in the G3TXQ folder.

Ignore the segment size warnings - the model produces acceptable Average Gain figures (< 0.4dB)and converges reasonably well.

I am working on a modified model with segment tapering which promises excellent Average Gain figures with fewer segments. I hope to be able to make it available within the next few days.

Any problems just email me direct

3500. Shortened 40m Hexbeam

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-11-06 04:07:44 UTC
From: km6cz
Topic: 3500 Message: 3500

Hi folks,

I was able to put together the 40m-10m hexbeam over this weekend. The use of RG-58U seems to work for the 40m elements although I did not get to put the antenna up. I tested the completed antenna on a patio table. 40m elements were difficult to tune, although I was able to get the SWR down to 3:1. The main difficulty was that the element spacing did not seem to work the same as with the wire elements. A short time after I completed the antenna, the XYL said no way is that going up on the roof. (The footprint was 25' across and immediately drew neighborhood interest..; even though I was building it in my driveway.) The size and added weight of the coaxial elements did require my redesigning the mast to baseplate and center support. (I used two cutting boards which worked ok for the baseplate, but the original center support using 1.25" Sch 40 PVC wasn't sufficient.)

In short, the concept seems to work, but will require some experimentation to determine the proper element spacing and more importantly, on the air testing to see if the 40m elements actually radiate, rather than act like a dummy load.

Unfortunately, I was not able to do much testing other than hooking up the MFJ-259 and adjusting the driven element once (from 5:1 down to 3:1 at 7.15 Mhz.. then the XYL veto.) I am now redesigning the antenna for the standard 20-10m configuration. The largest diameter fiberglass elements used (MaxGain) are fairly rigid; I plan on using shorter lengths of these and the smaller diameter rods to allow for greater bending of the spreaders. (There was not much bend where the 10,12,15m elements attached to the spreaders with the heavy fiberglass tubes.) All in all, this was an interesting experiment which shows promise. Lastly, I do have to agree with the XYL though, with the 40m elements, the hexbeam was as large as my TA-33M and more noticable to my neighbors.

73's

Phil

Phil,

Sorry to hear that the XYL didn't appreciate the "beauty" of the big
HexBeam :)

You say you had trouble tuning the 40m elements. I wonder what
parameters you were measuring, and what values you were trying to
achieve? I'm interested to know if you have done any work to predict
the impedances of the RG-58U version, and how they differ from
a "regular wire" version.

Regards,
Steve

3504. 5bands HB: comparation from some models

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-11-07 15:11:33 UTC
From: Giorgio
Topic: 3504 Message: 3504

I am not expert in antenna modelling AND I AM NOT SURE IF MY MODELS ARE CORRECTED, but I have tried to do a comparation from some 5 BANDS model with 4nec2 software:
- TOP FEED FROM DL7IO PDF BUILD WITH 4NEC2
- TOP FEED FROM G3TXQ EZNEC MODEL CONVERTED WITH 4NEC2
- BOTTOM FEED FROM LZ2BE.MAA MODEL BUILD WITH 4NEC2
- BOTTOM FEED FROM LZ2BE.MAA WITH MMANA-GAL for comparation with 4nec2

Some strange result:
- for lz2be model, SWR is lot of different from 4nec2 and mmana but gain not.
- Dl7IO model no give me any positive result, I think there is some of wrong in my NEc model but I do not find it.....

I have upload the file RESULT_IV3DDM.ZIP in files area.

Any comment is welcome!

Giorgio,

Some things for you to check:

1) Are the results all produced under the same conditions i.e. are they all in Free Space, or if they are above Real Ground are they all at the same height with the same ground conductivity and permittivity?

2) Are the wire guages the same for all models?

3) How good are the models? Do they have low Average Gains and are they convergent. [L B Cebik has useful information on his website about the accuracy of models] A quick look at the AGs of your models on 20m suggests that the DL7IO model is poor (1.39dB), the LZ2BE model is poor (1.16dB), and the G3TXQ model is acceptable (0.31dB)

4) Have you remembered to subtract the Average Gain figures from the Forward Gain figures?

K4KIO (Leo) and I have been doing a lot of work recently on optimising the modelling of HexBeams. One of our conclusions is that a "poor" model (which exhibits a high Average Gain)can still produce reasonably accurate Gain and F/B figures, but it will have very inaccurate Impedances, and hence SWRs.

It is particularly difficult to model accurately a 5 band HexBeam within the 500 segment limit of EZNEC, but Leo is currently working on a tapered-segmentation option which promises better accuracy.

Topic: 3504 Message: 3506

Giorgio,

Some further information.

Your DL7IO model is producing some very strange impedance values. You appear to have 5 transmission lines interconnecting the bands - there should only be 4 ! Also, DL7IO does not use 50Ohm coax for his interconnections, so you may not be accurately modelling his design.

73,
Steve G3TXQ

Hex up and on the air last night. Only 30 feet off ground. Big pile up from Europe. Worked several US stations on West Coast. Hex is much better than my old trap vertical. Will be on the air from 1500 to 1600 GMT on 14.245. This is a DX net and easer to make US contacts. If we make contact make sure you tell me you are using a HEX. I can also be on 17 meters. If this works we may be able to set up individual schedules. Have received many emails from HEX users so the DX net may be easer way to start. John XU7ACQ

Hi Steve, tnx for all your info.

Before your msg, I do not knew average gain test and now I have read the Cebik article but I have many difficult with english...

I have eliminate 1 TL in excess to dl7io model, swr is better but not good.

I know that lz2be and dl7io models haven't caoax for feed but I think TL can be used also for these models...

I will delete my file in FILES section because not accurate.

Georgio,

You might try increasing the impedance of the transmission line on the DL7IO model to about 200 Ohms and see if the SWR improves. Holger's models often used a higher impedance line than 50 Ohms.

Also, have you remembered to allow for the Velocity Factor of the coax cable - I don't know whether 4nec2 handles this automatically for you?

73,
Steve G3TXQ

John,
I'll be listening for you.
I have a Hex Beam on 20 Meters.
I am a bit confused, however, by your use of "tonight" -- Would that be tomorrow night in Cambodia? Right now it is 8:35 PM, November 8, here in NJ but that is 0136 hrs tomorrow, No vember 9, in UTC time. What's that in Cambodia?

Still trying to get a valid e-mail for John, KF4ZLO. All I know is that he left for Cambodia in early September and the e-mail address I gave to you was supposedly going to be valid.

Thanks
Have the local governments put any restrictions on his operating ? I think 15 or 20 meters would be the way to go. Keep me in the loop...I would like to work him. And I could use Cambodia as a contact.

Hi,

I have had the parts for a Hex Beam sitting around for a while now. I have some time on my hands and am ready to assemble the beam. I am following the K4KIO plan even down to the same cutting board hub.

I am intrigued by Leo's rotating mast at http://www.leoshoemaker.com/hexbeambyk4kio/step7.html. I have a 30 foot slip up mast available and a used Ham II rotor which still needs to be tested. The rotor is quite heavy and lends itself to a rotating mast implementation. That way the weight is at the bottom.

I wonder about the effect of rotation on the guy rings. A local ham friend did something similar with long 2 meter beams for weak signal work. Certainly the hex beam is similar to a long 2 meter yagi in wind loading. My friend said to use bearings on the guy rings because of friction and wear from mast rotation.

Certainly I can get by without the bearings in the short run. My initial plan was to use a cheap TV rotor at the top. But I already have the big rotor on hand. And the bottom mounted rotor does reduce the required guying strength quite a bit. Also the hex beam may not be rotated as much as the 2 meter yagi. From the west coast, most of the time the beam will be aimed east northeast. Also the hex beam has a very broad pattern compared to a 2 meter long yagi. There will not be the same amount of precision rotation.

I will be clamping a short PVC section at the roof edge (about 9 feet up) for the mast to rotate in. That means a single set of guys at the top may work for now. Later a second set and be added one section down.

I am looking for any experience regarding guy ring wear and tear.

I installed a 2 element Steppir on a flat roof with the rotator on the bottom for a friend, and used a TB-105 support bearing for the top guy ring. It's got eyes for the purpose, and works well. They can, apparently, be had from http://www.starkelectronic.com/rotor.htm .

I used the stock ring, mostly unloaded, for the middle guy, for a backup guy set.

Thanks Doug,

That could be just what I am looking for. From the pictures, it looks like there is a range of diameters. But I can't find any specs. I could use the TB-105 bearing at the top and bottom of the top section if needed. Two bearings could cover the top and 2/3 up from the bottom. And 1/3 up from the bottom I will let the mast rotate inside a short PVC pipe attached to the eaves.

I did a search and found another source. AES has it in stock as ECG TB105.

Now I hope my used rotor really works!

Again thanks for the info.

Ah, the inside diameter of the TB-105 is limited, but think it was maximum 1.5 inches, with a bit of filing of flashing to get that. So, if you used a standard pushup pole, you could use one of those at the top, and on the second section.

We used the bottom three sections of a 4 section pole (or maybe the middle three of a 5 section), since that was what he had; and we were restricted in only guying to the roof and I wanted to maintain a good angle on those guys.

That meant the top section was 1.5 inches, and we redrilled the mast to boom plate to accomodate an appropriate clamp, since the supplied one was for a 2 inch mast. The bottom section was 2 inches, so that fit the HAM-II well.

And I really like the Idiom Press Rotor-EZ add-on.

I have the 20 Meter Hex beam at 30 ft on a fiberglass 40-ft Wonderpole

(http://www.wonderpole.com/) with NO guy wires at all. The rotor is at the bottom and is a HyGain AR-40 (light duty -- see Hy-Gain QST ad). The whole mast rotates with no trouble whatsoever; and, with most of the weight at the botom, the fiberglass pole sways a bit but does not lose its heading, even in 50-60 MPH winds. Oh yes, the bottom section under the rotor is clamped into a GAP ground stake such as is used for tilt-over verticals.

3527. problem with Hex-beam measurements

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-11-13 13:50:10 UTC
From: johancmp
Topic: 3527 Message: 3527

I built a 5-band Hex-beam according to the exact measurements. For 20m the measurement is 5.52m times 2. The SWR on 20m was 2.8 at 5m above ground. I the started shortening the wire and eventually ended up in taking off 200cm per side, a total of 400cm overall. The SWR then came down to 1.2 Will I now lose on the db gain? Why did I have to take off so much? Will a 1 to 1 balun help to get the right measurements. I had to shorten all the bands. I used stainless steel wire.

John,

The Hexbeam produces its best F/B, and almost its best Forward Gain, at a frequency where its SWR is about 2.5:1 (perhaps a bit lower in a multiband array), so your first measurements look about right. The SWR should improve steadily above this frequency and deteriorate rapidly below it. Lots of folk make the mistake of tuning the beam for a good SWR, but you can easily throw away most of your F/B and a couple of dB in Gain this way. Take a look at:

http://www.leoshoemaker.com/hexbeambyk4kio/understanding1.html

for more info. You can either:

1) Live with the high SWR and use an ATU
2) Tune for a low SWR and sacrifice antenna performance
3) On a monobander, or a multibander with seperate feedlines for each band, reduce the SWR with a "Hairpin or Beta match"

What I cannot understand is that you have had to shorten the wires to improve the SWR - usually it's the other way round.

If you could tell us how the SWR varies across the band it might give a clue as to what is happening.

John,

One further thought, this time on your choice of stainless steel wire.

I'm not sure that this choice has much effect on the resonant length
of the elements, but you might want to take a look at:

http://www.cebik.com/wire/wiresize.html

where LB shows that you could be losing 0.5dB of Gain compared with
copper.

Topic: 3527 Message: 3530

John,

I just ran an EZNEC simulation of a 20m HexBeam at 30ft above ground with Copper wire and then with S/S wire, and got some surprising results. I used Cebik's conductivity figures. The simulation results would seem to reflect your practical measurements.

When I replaced the copper with S/S:

1) The frequency of best F/B dropped by over 100 KHz
2) The Forward gain fell by a massive 2.5dB
3) The SWR improved from 2:1 to 1.4:1

I was surprised by this until I looked at the relative conductivities of copper and S/S. S/S is 40 times worse! The feedpoint impedance of the HexBeam is relatively low, so currents are high and wire conductivity becomes more important. The improved SWR is simply a by-product of a more lossy array.

Please ignore my last posting about the shape of the SWR curve - using S/S produces a quite different set of values.

The simulation suggests that if you use S/S you would need to reduce the length of the wires to achieve the same resonant frequencies, and that you would end up with a "better than normal" SWR - pretty much what you are seeing.

My advice? Revert to copper wire - 2.5dB is too much gain to throw away!

Just a thought, .5 of a db = 1/12 of an s unit....vs corrosion and durabilty issues that can, will and do happen with copper. The durability problems resolved with stainless could out weigh the relatively small loss difference....unless you are seeking that last country for all band dxcc and he is so faint you can just tell he is there....Would 1/12 of an s unit matter even under those circumstances?..Interesting proposition...Stainless will out last the copper...and the coax feeding the antenna.FYI material doesn't change resonant length...length will be same but resistance can change with material differences,HOWEVER resistance is not resonance..Think about it...W4HV...Mike

Mike,

I completeley agree about the 0.5dB being insignificant.

But if you see my later posting, it seems like the loss could be more like 2.5dB on the HexBeam (0.5dB was the figure for a half-wave dipole), and that is getting to be significant.

Like you I would not have expected conductivity to affect the resonant length, but EZNEC predicted a 100KHz shift at 20m when moving from copper to stainless steel.

3535. Hex-Beam measurements

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-11-16 09:53:17 UTC
From: johancmp
Topic: 3535 Message: 3535

Hi Steve,
Just to let you know I did not shorten the reflectors, would that make any difference to the F/B. The reason I used the S/S wire is because I'm a 100m from the sea.
Txs so far for valuable info.
John - ZS1GP

John,

This is a repeat of my private Email, in case it's of interest to other Group members.

Take a look at:

http://www.leoshoemaker.com/hexbeambyk4kio/understanding2.html

It's essential to get the HexBeam Reflectors self-resonant at the frequency where you want best beam performance. The Driven element dimensions are less critical - they mostly affect the SWR.

You need to trim the Reflector until its impedance is R+j0 at your frequency of interest. When you tune the Reflector it must not be influenced by the Driven element, so either take the Driven element off the antenna temporarily or make sure it is Open Circuit at its centre. Remember, too, that if you measure the Reflector impedance through a length of coax with your MFJ there will be an impedance transformation caused by the coax. You'll either have to cut the length of the coax to be an exact number of electrical half-wavelengths, or do what I do and use a transmission line calculator to tell me what the Reflector impedance is from the analyser reading. Once you've got the Reflector right, measure its length and simply make the Driven element 2% shorter.

I hope that makes sense and answers your question - it's easier to do than to describe in words :)

Actually..I have looked at L.B.'s work many times before...The point was the that 1/12 of an s unit is not worth fussing over!!...I happen to disagree with cebik on some points ...He unfortunately isn't around to debate this issue...obviously this is one of the points we disagree on and thats okay....Since its 1/12 db I guess if you were running 1000000 giga watts it could be important...Thanks

Additionally cebik equates resistive components to resonant impedances...See the article to which you refer...His is errant thinking...It matters to your impedance matching but not to the actual resonant (radiator) component...By cebiks theory you have to shorten the length as conductivity goes down(more accurately understood as resistance goes up)This shortening is proportional in reality to the loss of resonance to compensate by shortening of the radiator and therefore presents in cebiks data as a loss...Again just think about this point...Data in cebiks chart reflects his idea of keeping a 50 ohm match when modeling...I also add modeling is nice but understand it operates within specified program parameters....When you limit the possibility to a 50 ohm(or 52 ohm match) you eliminate the truth...I would settle for 1/12 of a db loss anytime to get the long term performance of stainless. However if you can live with a 57 ohm match the point is moot..The losses are negligible in both models..and the wire length comes back to resonance...The transmitter won't be bothered as coax variance could just as easily create a 57 ohm down to 45 ohm match for the rig to see...I have measured hundreds of miles of it and believe me it varies...Proof to me the world is get it close because its never perfect or as modeled....W4HV ...Mike

3540. Hex Beam Bi456 is up and running

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-11-16 13:09:16 UTC
From: John Keller
Topic: 3540 Message: 3540

At last it's up; first contact ER4DX, Vasily, in Moldova for a new country.
Set at 37.5' on a home made wilson type crankover tower.
Turning with a Yeasu G 450A rotor.
Did need the SB220 to get through: gave 5X9 rcvd 5X6.
Seemed to hear a db or so better than my Tribander Beam at 53' with a little more noise as well. However 20m has been noisy in general on the TET lately. So not sure noise is due to the Hex Beam or the band conditions.
The Beam is easily enough to assemble and has much ingenuity in the design and some ingenious parts to make it all work. All in all a fun experience. As the assembly went along I wondered how many trips to the hardware store or internet it would take to home build it. I would think a mono bander twenty would be the way to get started and then add others as time permits.
It's the first "new" antenna I have put up. The TET was used cost $100 and got a parts antenna for $30. So the cost for the 5 Bander Hex seemed less high to me.
Any who hope to catch some of on the air for the hex to Hex Contact:-)

Mike,

I hesitate to keep the discussion running, but you raised some interesting points which sent me back to the text books :)

A few thoughts:

1) I understand the point you are making about Cebik's data. But in my own simulations I have not bothered about the feedpoint RESISTIVE component - I have simply looked for ZERO REACTANCE, and that definitely required a small but measurable change in length when going from copper to S/S. I appreciate that you have some concerns over modelling results, but remember this discussion started because a chap building a HexBeam with S/S found he had to shorten his wires compared with published dimensions.

2) I have been doing some calculations to see if skin depth could be a possible cause. As bulk resistivity goes up, the skin depth increases and the effective diameter of the wire reduces. At 14 MHz, changing #16 gauge wire from Copper to S/S increases the skin depth by the equivalent of 2 wire guage steps, so it could be significant.

If I model a Hexbeam driver made of #16 gauge copper and find its resonant frequency, then swop to S/S, the feedpoint impedance goes from (24 + j0) to (33 + j7.5). I presume the increase in bulk resistivity is causing the increase in the Real component from 24 to 33 Ohms, but there is also an inductive reactance being introduced that requires a shortening of the wire to restore resonance. If I revert to copper, and then reduce the wire size from #16 gauge to #18 gauge, the impedance goes from (24 + j0) to (25 + j3.3). Moving to #20 gauge takes the impedance to (25 + j6)

In other words, changing from copper to stainless steel seems to introduce the same sort of inductive component as reducing the wire diameter, and this reduction in wire diameter matches quite closely the calculated increase in skin depth.

3) Mike, you continue to refer to a loss of 1/12 dB. My original posting quoted Cebik's 0.5dB loss for a dipole, and I later quoted 2.5dB loss for a HexBeam, so I don't know where your figure of 1/12dB comes from??

73 and enjoy the weekend!

Steve G3TXQ

Indeed...I enjoy lively friendly exploration Steve...I wanted you to know 1/12 OF AND S UNIT is EQUAL TO .5 DB...I never said 1/12 db .But I was referring to cebiks (and your) quoted dipole losses.Please note if you check the program you are using the material difference could easily be predicated on cebiks tables (which would cause them to agree with his work)..That's the difference...and that amount of loss is negligible.Your own search for for matching with zero reactance causes the shift as well.I find this interesting. Thanks for the talk! Hopefully all our members learn from it..I am an RF engineer with 33 years experience.I also hold several patents here in the states..8 of which are for antenna and related designs. I am not always right but usually can give sound advice. You are doing a great job!!! W4HV .Mike

Mike,

Thank you for the gracious comments. I, too enjoy the "cut and thrust" of technical debate!

Re-read your recent postings and you'll see that you DID say 1/12th dB, but I guess that was a slip of the "keyboard":)

Mike, I would genuinely value your views on the following phenomenon:

When I model a linear half-wave dipole (i.e. wires in a straight line), if I reduce the wire diameter the resonant frequency moves upwards - i.e. the wire has to be made slightly longer to achieve resonance at a particular frequency. This seems to be in agreement with all the textbooks.

If I now bend the dipole into the shape of a HexBeam Driven element the opposite happens. i.e. if I reduce the wire diameter the resonant frequency moves downwards. I don't think this is just a modelling aberration - I've measured the same thing in practice.

The effect seems to be dependent on the included angle between the two halves of the element, and if you model a shape with an included angle of about 95 degrees (somewhere between a linear dipole and a Hex Driver) the resonant frequency is pretty much independant of wire guage.

Have you any ideas on what might be causing this effect?

PS I'll out-bid your 33 years with 39 years in Radio Communication design with the BBC, the UK DoD and the UK Foreign Office .... but hey, that just makes me feel old :)

73,
Steve G3TXQ

Steve , It makes me feel old also...fortunately I started at age 13 with my first designs....so I guess you have the years in a couple ways...LOL !...The reaction of the apparent resonant frequency in changing diameters is a well documented truth..I have always thought of the opposing(the actual opposing cross sectional side) sides of the wires as a form of capacitive reactance.Since there is no RF current flow in the inner part of the wire and since in larger wires the "plate area" is increased.(also the radiation resistance is decreased, thereby increasing radiation efficiency)..I know that sounds weird but it is how I model in my head before I began using a program...As for the hex, bending the element wires is going to do exactly the opposite (introduce inductive reactance)which would tend to cancel the effect created by the wire diameter..While an empirical study would need to be made to confirm this train of thought I feel it may be a validatable theory.. I think in the bending there is a coupling effect that may explain the aberration. This could be true because the resonant length is out of phase at various point..The effect would be created due to the apparent length if the wire were straight being different than the peak to peak length of the wavefront actually being radiated..The angle of the bend would affect this coupling and possibly explain you observations. Those are just my open thoughts on the subject..I hope this helps some in your process...It has worked well for me in my designs over the years....Its just how I visualize the lumped components inherent in Rf radiating circuits(most of us call antennas).

Mike,

I guess the trick is to grow old gracefully :)

Thanks very much for your thoughts - I'll need to read them through a few times to "digest" them. I, too, have tried to picture the various capacitive couplings and inductive effects, but couldn't quite explain the observed changes.

Mike, I reckon that we're allowed to get a little nostaligic. I just got off Ebay some 1958 radio magazines that contained the article from which I built my first 3 tube TRF receiver. And I also got a 1950s crystal set I was given for my 10th birthday. ..... but what will I ever do with them :)

73,
Steve

Well I agree...The trick for me is growing old at
all...I am also a cancer survivor...5 yrs now!!! I
understand you facination with old "goodies." I have a
few myself...They work with my antenna systems today
much better than when high SWR meant you were getting
burns on your lips off your D-104 if you were
fortunate enough to have one...No meter ...no need
..If you can hear me it works...LOL!
Well better close this line before we are so off topic
we get banned...I hope the tech thought process helps.
My engineering friends say I see RF the same way Tesla
did. Its in my head (possibly why I seem a little
different) 73 W4HV Mike

3547. ugly hex..

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-11-19 01:25:08 UTC
From: hambeemer
Topic: 3547 Message: 3547

Howdy!
Once again I have made another Hex. Multi bands of 20,17,15, 12 and 10 meters. Used house multi strand wire with the coating still intact. I think the wire is #12.
We have a store here that sells salvaged stuff and purchase fiberglass poles that are real stiff.
I cut the wires figuring I would be pruning them so I have no idea what the measurements are! HEH. SWR is flat on all bands.
Knowing the discussion of the need for some SWR to get more F/B has had me wondering.
HOWEVER! November 8 I turned the antenna to the east hoping to hear my friends in New Jersey. I did hear something and thot I was hearing mexico until the call signs were said...
Italy of all places! this was on 15 meters/21.285 So I waited for the fellow to call cq and called out my ab0ts.
I didn't hear anyone calling him but he told the rest to hold on as he was calling alpha bravo zero tango sugar... Cool!
He said my signal was 5 by 2 not bad for the hex which is up only 20 feet and 100 watts. Of course he was up 75 feet and had a typical 5 band yagi.

So either my calculations are real good or the bands are starting to open up?

Not sure if I want to tinker with sucess! heheh

I was wondering if part of the problem was the use of the stainless
steel wire?

Mike and Steve,

Interesting discussion. FWIW, NEC2 has a problem with acute angles. This has to do with how the author implemented the method of moments computations. In short, the issue is that any segment on the driven element actually radiates a portion of its flux to all parts of the other three legs of the driven element (field strength and phase varying at each of the other affected segments). A portion of the induced current is combined with the direct driven current in these segments and so on, which thereby modifies the ultimate radiated field. The actual composite field becomes a complex iterative computation (that can converge), which NEC2 is ill suited to handle. The reflector computation has similar issues.

Mike, hope you continue to beat the cancer and that we all can ham for many more years.

3551. Anyone experience detuning when near trees?

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-11-20 02:24:25 UTC
From: Mark
Topic: 3551 Message: 3551

The baseplate I made using 1/2 inch pressure treated plywood didn't hold up to the stress of the spreaders. I've rebuilt it with a 1/2 inch thick polyethylene cutting board.

However since I've rebuilt it the SWR seems inordinately high running 2-3 across the bands as compared to my previous version which were much more similar to Traffie's version. The other difference is that it is now mounted very close to a tree and previously it was 3 or 4 feet away (approximately 1 - 1.5 meters).

Has any one experienced this? I've tried rotating the beam while watching the SWR but found no differences. I also swept it with a friends MFJ analyzer but found no distint SWR dips.

I have alse read the recent posts about having some SWR is good which I find quite interesting.

Ed,

You are right - there are some conflicting dimensions out there!

Leo (K4KIO) and I have been trying to produce a definitive set of dimensions for the benefit of builders. I think we're happy with the monoband dimensions we have, and Leo is presently looking at multiband dimensions.

The problem is that the HexBeam is relatively narrow band compared with a "full-size" parasitic beam and so it's important to get it resonant at your frequencies of interest. I would strongly recommend you actually tune it in your environment. Take a look at:

http://www.leoshoemaker.com/hexbeambyk4kio/understanding1.html

for more info.

If you could tell us:

1) What wire gauge you'll be using
2) The final height above ground for the antenna
3) The spacing between the two band elements
4) Where your interests are on 20m e.g. CW or SSB

we can give you a start point.

73,
Steve

Barry,

Thanks for the input on NEC2 limitations.

From the day I started trying to model the HexBeam I saw how critical the segmentation needs to be around the acutely angled feedpoint. I found that "tapered" segmentation here helps a lot. I guess this feature of the modelling is explained by your comments.

Over the past couple of weeks I have built a 10m beam purely for experimental purposes, and have been comparing measured impedances and azimuth patterns against EZNEC predictions. The agreement is good enough for all practical purposes.

Interestingly the EZNEC impedance predictions are VERY accurate for one element (i.e. the Driven element alone, or the Reflector alone); they are a bit less accurate for the complete beam - the Resistive component tends to be a bit high, and the Reactive component a little low - but are still perfectly useable. Within the limits of my test range the azimuth pattern predictions are in very close agreement.

The only significant discrepancy is that EZNEC predictions are consistently 1% or so high in frequency - a bit more than I can account for by the vagaries of centre post connections etc. I've chatted to Roy Lewallen about it but he has no explanation. So for now I simply "scale" the frequency axis!!

3555. Traffie Hex Beam Power Handling

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-11-22 04:22:58 UTC
From: K7PEH
Topic: 3555 Message: 3555

I just realized that I don't really know how much power the Traffie Hex beam (five bander) can
handle. I checked at the Traffie web site and did not find any figures for power handling capability. I assume legal limit as I have pushed through 1400 watts without any apparent problems.

So, I figure that any limitation is in the coaxial connection and not the wires themselves. Does anyone know anythings specific? Has anyone pushed more than 1500 watts into a Hex Beam (Traffie) -- experimental operations of course.

phil, K7PEH

P.S. Also, I noticed that there was some notes about Traffie possibly selling the business. I
know that this is probably old news but does anyone have updated information?

Thanks Steve,
I have seen the very good Leo's page, and the
excellent "Understanding..." (is it yours?)
I am on your side regarding tuning and I hope my MFJ analyzer will
help me on the job. I'm working on baseplate, spreaders and balun
(Collins choke) now.
1) I would like use AWG16 pvc coated electrical wire but I will
purchase different wire if it would be better
2) Height will be 25 feet
3) I prefer 14-18MHz CW tuning
4) I really would like more bands in the future so spacing might be
as suggested by K4KIO
Thanks again Steve, 73's Ed IV3TQE

3557. Re: Hex beam measurements

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-11-22 15:11:51 UTC
From: Steve
Topic: 3548 Message: 3557

Ed,

Here are some starting dimensions for a 20m/17m beam using 16 gauge bare copper wire at a height of 24 ft:

20m
Half-driver: 216.6" [5502mm]
Half-reflector: 221" [5613mm]
Driver insulator: 7.7" [196mm]
Reflector insulator: 5.0" [127mm]

17m
Half-driver: 168.2" [4272mm]
Half-reflector: 171.6" [4359mm]
Driver insulator: 6.1" [155mm]
Reflector insulator: 4.0" [102mm]

The dimensions are optimised for the CW end of 20m.

Be aware that if you use insulated wire all the dimensions will change.

And remember to "cut long" and tune the Reflectors "in situ"

Good luck with the construction!

73,
Steve G3TXQ

I happened to be talking to Mike Traffie this morning and the subject came up about power capacity. He said that it should have no difficulty in handling full legal power.

I have put the legal limit in my five band'r many times...
No ill effects. I routinley run about 7-800 watts on ssb

3562. Testing 5bands Hexbeam

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-12-04 14:24:07 UTC
From: Giorgio
Topic: 3562 Message: 3562

Yesterday I have done first test on my homebrew 5band hex-beam, build on lx2be design (I had already start build and cutted wires some mounths ago).

Hex-beam is now in the garden at about 5 meter on the ground, and my vertical 12avq is at about 4 meter on the roof, at about 10 meter on the ground.

On Hex-beam SWR is 3,00:1 on 14 Mhz and 1,3:1 to 2,00:1 to other bands but signals in 20 and 15 meters (10 meters not tested) are better (S1-S2)on vertical 12avq than Hex-beam and also directivity is very small.

Can I Hope to obtain better result than vertical antenna, putting my hex-beam on the roof, or already now hex-beam should do work better than vertical?

Thank for any reply
73 Giorgio iv3ddm

3563. RE: [hex-beam] Testing 5bands Hexbeam

From: ARLHS / USCGA
Topic: 3562 Message: 3563

Something is not right.

My hex out-performs my 12AVQ in every way.
My hex is also 5 meters on the ground and has a 9 db gain over the vertical.
The SWR on 20 meters is 2.5:1 at 14.000 but drops to 1.5:1 from 14.100 and
stays flat through 14.350. The front-to-back is about 18 db on 20 meters. I
havent tested on other bands long enough to make any comparisons.

Suggest you check the spacing (very critical) and the element length (also
critical).
Most users say the hex works best at 20-25 feet above ground. I have not
heard many users say that a vertical is better.

ditto
Mine has some pretty good nulls off the sides. The front to back is only
about 5 db
But it certainly hears better than my vertical. And about 3-4 S units better
than my dipole..on 20 meters.
good luck
JohnB

Hi Giorgio,

I believe lz2be`s design uses insulated wire for the elements.
Perhaps your insulation (or wire) properties are a little different?

Even a fairly small amount of difference will shift everything quite
a lot.. as i found when i fitted some very small wireclamps at the
element knee`s to prevent the wires redistributing themselves in very
high winds.

The performance and swr have suffered quite considerably since the
modification.
I`ll have to do some retuning the old fashioned way, (no mfj 259) but
at least it`ll keep me fit :)

I think it`s a good idea to do as Steve (G3TXQ) suggests and check
the reflectors are resonant at the required frequency before
adjusting anything else.

Giorgio,

As others have said, something is wrong.

My HexBeam is about 6.5m above ground. The F/B ratio is consistently 18-20dB, with deeper nulls to the sides. If you are not seeing this sort of directivity, the beam isn't working properly.

As Colin says, a good first step is to check the resonant frequency of your Reflectors.

Hey, I was looking at the hexbeam website, it talks about a 4030i model being in development. I wonder if you can tell me when it might be available, and any specs that might be available?

Also, is there a 40m only version? I didn't see it on the website.

I get the feeling this might be a hex beam hobbyist forum rather that a forum for the hexbeam company, is that right?

Thanks for any pointers,

Jeff KA6LAF

J,

1) 40m hexbeam dimensions: close on 19ft from the centre post to the tips of the spreaders

2) I think I have heard other Group Members mention that Mike Traffie tends not to communicate via Email, but is happy to take 'phone calls. There is a 'phone number on his website.

From: Steve
Topic: 3576 Message: 3577

John,

At 85 ft the elevation pattern is breaking up into several narrow lobes, and the answer to your question is "band dependant".

An EZNEC run gives the following results for a 5 bander with the 10m elements at 85 ft above average ground:

14MHz: lobe1 11deg; lobe2(-1.6dB) 36deg; lobe3(-5.7dB) 72deg

18.1MHz: lobe1 9deg; lobe2(-1dB) 28deg; lobe3(-2.3dB) 51deg

21MHz: lobe1 8deg; lobe2(-0.9dB) 24deg; lobe3(-2.1dB) 43deg

24.9MHz: lobe1 7deg; lobe2(-0.6dB) 20deg; lobe3(-1.4dB) 35deg; lobe4 (-2.6dB) 54deg; lobe5(-6.6dB) 86deg

28.4MHz: lobe1 6deg; lobe2(-0.5dB) 18deg; lobe3(-1.1dB) 30deg; lobe4 (-1.7dB) 45deg; lobe5(-2.8dB) 66deg

The figures in brackets give the strength of the lobe relative to lobe1.

Be aware that there are some very deep "nulls" between these lobes at elevation angles you might well be needing for shorter skip paths!

Hope this helps,

Steve G3TXQ

3579. Re: Take-off Angle

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-12-14 14:11:45 UTC
From: Steve
Topic: 3576 Message: 3579

John,

Sorry to say, it will be little different at 80ft. The first two lobes are as follows:

20m: 12deg & 38deg
17m: 9deg & 30deg
15m: 8deg & 26deg
12m: 7deg & 21deg
10m: 6deg & 19deg

This is not peculiar to the HexBeam - a dipole exhibits very similar elevation patterns at the same height.

But remember that the height is very worthwhile at low (DX) take-off angles. For example, on 20m at the low take-off angles typical of long distance work, the beam will have about 6dB more gain at 80ft than at 30ft.

They say a picture is worth a thousand words, so I've posted two elevation plots in a document on my website at:

http://www.karinya.net/Hex_elevations.doc

The red curve is the 20m performance at 80ft, and the blue curve at 30ft. This shows clearly that although at 80ft there is a deep null at about 25 degrees, at low angles (less than 10 degrees)there is a considerable advantage over the performance at 30ft.

So I guess the "optimum height" all depends on the sort of path length you are interested in!

3580. Re: [hex-beam] Re: Take-off Angle

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-12-14 22:17:46 UTC
From: John Cowan
Topic: 3576 Message: 3580

Steve:
Thanks for the graphics. Helped me understand the take-off angles better. I use my Hexbeam for DX. I am quite satisfied with the results. I needed the take-off angles for a propagation prediction program.

John W0TMM

Steve <steve@...> wrote: John,

Sorry to say, it will be little different at 80ft. The first two lobes are as follows:

20m: 12deg & 38deg
17m: 9deg & 30deg
15m: 8deg & 26deg
12m: 7deg & 21deg
10m: 6deg & 19deg

This is not peculiar to the HexBeam - a dipole exhibits very similar elevation patterns at the same height.

But remember that the height is very worthwhile at low (DX) take-off angles. For example, on 20m at the low take-off angles typical of long distance work, the beam will have about 6dB more gain at 80ft than at 30ft.

They say a picture is worth a thousand words, so I've posted two elevation plots in a document on my website at:

http://www.karinya.net/Hex_elevations.doc

The red curve is the 20m performance at 80ft, and the blue curve at 30ft. This shows clearly that although at 80ft there is a deep null at about 25 degrees, at low angles (less than 10 degrees)there is a considerable advantage over the performance at 30ft.

So I guess the "optimum height" all depends on the sort of path length you are interested in!

John

Since it depends on the height and the antenna type and the ground conditions, the best way to answer this is to model it using something like EZNEC software.

I have been planning to do something like this myself, but have not yet had the time. I am on vacation the next two weeks so will try to see what I can come up with, once I catch up on the honey-do list. :)

James,

A good starting point would be Leo's HexBeam website:

http://www.leoshoemaker.com/hexbeambyk4kio/general.html

It has lots of practical advice, including dimensions, and some of the background theory. There are also some links to other HexBeam websites.

Don't be afraid to come back to the Group with further questions :)

James,

It's not hard, Leo's site has lots of good info on it and I referred back to many times during the construction of mine. Especially the theory about it. Read it and re-read it and then re-read it again. Just when your totally confused and your in the middle of constructing the thing it starts to make sense, and after you get it up in the air it's all clear as mud.

I have been aquiring the parts over the last 6 months, mine used Flex Weave wire I got at a ham fest from a vendor from Long Island, NY. I used Crappie fishing poles from Harlee Rods, Jersey City, NJ, I paid $4.99 each for the spreaders (btw they are very thin and will break if you bend them too much, I broke 2, a 1/2 piece of plywood from a coax reel, a scrap piece of 2.5" PVC, some poly cloths line, RG8 for the feed network, scraps of plexiglass for the termination points of the feeder. It took me a good weekend to put it together, I'm not fast nor am I slow, I'm only half fast. :)

Leo's specs appear to be geared to the phone parts of the bands and that's where I set mine for. It works great! Far better than the Butternut Butterfly I took down and a whole lot easier to adjust! If you have access to an MFJ Antenna Analyzer use it when your tuning it. I still have to pull mine down in the spring and I'll rebuild it with better glass poles and really adjust the tuning of the reflectors better. For now it's up on my old Wilson TT45 crank up tower, fed by new RG213.

If you can handle a drill, wire cutters, soldering iron, read and understand the written word, then you should be able to build this antenna.

Topic: 3548 Message: 3586

Terry,

I don't know of anyone who has built a "7 bander", but a starting point would be Leo's 5-band dimensions at:

http://www.leoshoemaker.com/hexbeambyk4kio/specsandfaqs.html

then add:

30m Reflector 309.8" (insulator 6"), Driver 305.2" (insulator 9.3")
40m Reflector 446" (insulator 8.6"), Driver 437" (insulator 13.4")

These 30m and 40m dimensions are monoband figures and would probably need to be shortened slightly as part of a multiband array - the presence of the other wires typically detunes them down in frequency.

I guess it's good weather for "playing antennas" in VK-land at the moment unlike the Northern hemisphere :)

Happy Christmas!

Hello Terry,
you also can try my webpage.
www.hexbeam.de
There are a few designs based on 40m that go up to 12m.
As more bands you add as more difficulties it makes to calculate/model
the antennas.
Because of the shape of the spreaders the higher bands are very close
together installed which causes bigger influence and makes it hard to
optimise the antenna.
But there should be enough information for the start on the mentioned
pages.

Terry,

One further thought. In addition to looking at Holger's and Leo's sites, you might want to take a look at:

http://www.linehand.com/k7hc-MegaHex.htm

where you'll see some photos of Clay's 40m/30m hexBeam project. This is how big yours will be!

One word of warning ..... before visiting Clay's site wear some ear plugs :)

Welcome aboard!

A variety of materials have been used successfully by hex beamers. Probably, you are going to have to just try yours and see how it comes out, unless someone on the user group has some direct experience with the "steam treated bamboo."

Information on other aspects of the hex beam is available on several sites. Mine is http://leoshoemaker.com/hexbeambyk4kio/general.html and it contains links to some of the most popular sites of others.

Good luck and 73,

Leo, K4KIO

Curious what type of masts that folks with 5-band hex's are using. The rather small slot in the HX-5Bi's base plate makes it tough for larger rotors. I am looking at using conduit pipe since the hex has so little wind load but would like to know what others are using. Thanks!!

Hi Dennis,

I am using rigid steel pipe for mine that has a taper connecting a larger pipe for the rotor end and a smaller pipe for the Hexbeam end. Make sure you drill a hole through both pipes at the thread so that you can put a bolt through it to keep it from twisting in the wind.

3596. Re: Antenna Mast

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-12-28 09:09:45 UTC
From: Steve
Topic: 1906 Message: 3596

Dennis,

I use a single 20ft length of steel 2" diameter "scaffold pole".

It is supported against the end of my garage using 18" standoff brackets to clear the roof overhang. These 2 brackets are positioned at heights of 3ft and 12ft - I could have gone higher with the top one, but I wanted a good few courses of brickwork above it! I have one further short bracket supporting the mast off the top roof timber.

A Yaesu G450 rotator sits directly on top of the scaffold pole. The extended Hex centre post fits snugly in the rotator if I use the packing pieces supplied with it for smaller-diameter masts.

This arrangement places the 20m element somewhere around 26ft above ground.

I haven't found a need to guy it - there's relatively little extension above the top support bracket.

It's a very modest installation compared with some of you folks, but it keeps the neighbours happy!

73,
Steve G3TXQ

3597. Re: Antenna Mast

Yahoo group: hex-beam (2001 — 2006)
Date: 2006-12-28 13:40:52 UTC
From: rkbower
Topic: 1906 Message: 3597

Dennis --

My installation resembles Steve's in some ways, but with a twist...

I have a ground based, homemade mini-tower, that holds a Yaesu G-450 Rotor and thrust bearing. There is an approximately 48" length of 2" O.D. PVC going from the Rotor through the thrust bearing and extending about 10" above the thrust bearing.

The mast, then, is two (2) 10' pieces of Radio Shack antenna mast that slip together -- the mast is 1" O.D. The homemade Hex Beam (K4KIO Design) sits on top of the upper piece of mast.

It just so happens that with the specific installation location, there is a garage roof edge at about the 15' point above ground. I constructed a standoff that holds a piece of 1-1/2" I.D. PVC Pipe in a vertical position and the antenna mast slips neatly through the vertical PVC pipe making for a good physical support as well as allowing for easy turning as the ground-based rotor turns the entire mast.

I did not want the Hex Beam extending too far above the roof line -- the 20M element is approximately 25' above ground. To account for the 48" of PVC mast in the mini-tower, I cut 48" off the bottom section of mast. Then the 1" O.D. mast fits inside the 2" O.D. PVC above the thrust bearing and is attached with a 1/4" x 2-1/2" bolt through bost pieces.

If you send me your email address, I would be happy to send pictures.

Also, if you want to consider building your own mini-tower, I can assure you that it is much simpler than you might first think. When you really stop to think about it, the entire purpose of the structure is to hold the thrust bearing at some reasonable distance above the rotor. Once you realize that concept, then the construction just falls into place. The structure will cost less that the rotor and will make the rotor last almost forever. I'm no metal worker and constructed the tower over a weekend using aluminum angle and straight stock from Home Depot and bolting together with 1/4" hardware. The only tools required were a hacksaw, electric drill, tape measure, and socket wrench.

One final note, for the entire group, while it is very true that the Hex Beam has little wind resistance, mine definitely has a wind bias -- I can not understand why, buy mine really wants to consistently turn counter clockwise in any wind. If I free the mast to turn, the antenna will quickly wrap itself in a counter clockwise direction in even a moderate wind.

Has anyone else noticed this phenomena ?

I used the push up mast from Mike Traffie with a radio shack tv rotator at the bottom of the mast. There should be some pictures of the installation in the pictures folder.

Thanks to all who replied. These all help. I have a Glen Martin RT-424 roof tower that I intend to use and wiil try a 6' section of steel electrical conduit for the mast support. I suspect it will work fine. Thanks and happy New Year to all!

Dennis
I have a Glen Martin tower also. It is the 8' tower. The rotator mounts at the 4' level and I have a thrust bearing at the top. I have the top 2 sections of a 40' push up mast mounted in the rotor, with my antenna (spider Beam)mounted on the top of the push up pole. I have guys at the 10' and 20 level on the mast. The rotor is a Hy-Gain CD-45-ll. the set up works great but is a pain if you have to work on the antenna. We just had a storm come through Xmas night with sustained winds of 40 MPH and gust up to 60 MPH. I wish that I could say every thing came through OK but that is not the fact. One wire came loose, I think it is one of the 15 meter radiator, and I think that the antenna is free Wheeling now. As soon as I can get some Friends over we will take it down and find out what damage was really done. The point of all of this is that the set up is a great one and you wil be very happy with it.

Thanks Gene - sorry to hear about the antenna damage. Hopefully it will be easy to repair. One thing that makes this set-up a little less desirable is the need to climb the roof! The pitch on my house is fairly steep so I'm not looking forward to that. Luckily, I know a couple of Hams that are fire fighters - they climb roofs for a living!!! Take care and Happy New Year!

Yes, it sure was a pile up but my trusty old bb-hex at only 16ft still managed to get thru on 18/21/24 and 28 mHz.
